Questions regarding the Summary of Pesticide Use Report Data or information regarding the availability and cost of the computerized database should be directed to: Department of Pesticide Regulation, Pest Management and Licensing Branch, P.O. Box 4015, Sacramento, California 95812-4015.Telephone (916) 445-4038 or email questions to <mvotaw@cdpr.ca.gov>.

Order Form

To continue to make the *Summary of Pesticide Use Report Data* available, it is necessary to charge for the costs of reproduction and mailing. The reports can also be downloaded free of charge from the Department's web site.

The 1989 - 2007 *Summary of Pesticide Use Report Data* indexed by chemical or commodity reports can be found on DPR's web at www.cdpr.ca.gov. The *Summary of Pesticide Use Report Data* is available in two formats. One report is indexed by chemical and lists the amount of each pesticide used, the commodity on which it was used, the number of agricultural applications, and the acres/units treated. The second report is indexed by commodity and lists the chemicals used, the number of agricultural applications, amount of pesticides used, and the acres/units treated.

The Annual Pesticide Use Report Data (the complete database of reported pesticide applications for 1990-2007) are available on CD ROM. The files are in text (comma delimited format).

Please use this form to order reports and enclose payment to the address below.

I. INTRODUCTION

DEVELOPMENT AND IMPLEMENTATION OF THE PESTICIDE USE REPORTING SYSTEM

This 2007 *Summary of Pesticide Use Report Data* includes agricultural applications and other selected uses reported in California. The report represents a summary of the data gathered under full use reporting. The Department of Pesticide Regulation (DPR) uses the data to help estimate dietary risk and to ensure compliance with clean air laws, as well as ground water protection regulations. Site-specific use report data, combined with geographic data on endangered species habitats, also help county agricultural commissioners resolve potential pesticide use conflicts. Detailed, individual pesticide use report (PUR) data may be obtained from DPR for in-depth, analytical purposes.

Under full use reporting, which began in 1990, California became the first state to require reporting of all agricultural pesticide use, including amounts applied and types of crops or places (e.g., structures, roadsides) treated. Commercial applications–including structural fumigation, pest control, and turf applications–must also be reported. Pesticide use reporting is explained in more detail below.

TYPES OF PESTICIDE APPLICATIONS REPORTED

Partial reporting of agricultural pesticide use has been in place in California since at least the 1950s. Beginning in 1970, anyone who used restricted materials was required to file a pesticide use report with the county agricultural commissioner. The criteria established to designate a pesticide as a restricted material include potential hazard to:

- public health;
- farm workers;
- domestic animals;
- honeybees;
- the environment;
- wildlife;
- other crops.

With certain exceptions, restricted materials may be possessed or used only by, or under the supervision of, licensed or certified persons, and only in accordance with an annual permit issued by a county agricultural commissioner.

In addition, the State required commercial pest control operators[1] to report all pesticides used, whether restricted or nonrestricted. These reports included information about the pesticide applied, when and where the application was made, and the crop involved if the application was in agriculture. The reports were entered into a computerized database and summarized by chemical and crop in annual reports.

[1] Pest control operators include those in the business of applying pesticides such as agricultural applicators, structural fumigators, and professional gardeners.

With implementation of full use reporting in 1990, the following pesticide uses are required to be reported to the commissioner, who, in turn, reports the data to DPR:

- For the production of any agricultural commodity, except livestock.
- For the treatment of postharvest agricultural commodities.
- For landscape maintenance in parks, golf courses, and cemeteries.
- For roadside and railroad rights-of-way.
- For poultry and fish production.
- Any application of a restricted material.
- Any application of a pesticide with the potential to pollute ground water [listed in section 6800(b) of the California Code of Regulations, Title 3, Division 6, Chapter 4, Subchapter 1, Article 1] when used outdoors in industrial and institutional settings.
- Any application by a licensed pest control operator.

The primary exceptions to the use reporting requirements are home and garden use and most industrial and institutional uses.

HOW PESTICIDE DATA ARE USED

DPR undertook the expansion of use reporting primarily in response to concerns of many individuals and groups, including government officials, scientists, farmers, legislators, and public interest groups. It was generally acknowledged that the system for estimating dietary exposure to pesticide residues did not provide sufficient data on which to make realistic assessments; this often resulted in overestimates of risk. Farm worker representatives were also asking for more information to determine exposure and potential risk to those who handle pesticides or who work in treated fields.

There are several key areas in which data generated by full use reporting are proving beneficial.

Risk Assessment

Without information on actual pesticide use, regulatory agencies conducting risk assessment assume all planted crop acreage is treated with many pesticides, even though most crops are treated with just a few chemicals. If the assumptions used by regulatory agencies are incorrect, regulators could make judgments on pesticide risks that are too cautious by several orders of magnitude, reducing the credibility of risk management decisions. The use report data, on the other hand, provides actual use data so DPR can better assess risk and make more realistic risk management decisions.

After the passage of the federal Food Quality Protection Act (FQPA) in 1996, complete pesticide use data became even more important to commodity groups in California and to the U.S. Environmental Protection Agency (U.S. EPA). FQPA contains a new food safety standard against which all pesticide tolerances must be measured. The increased interest in the state's pesticide use data, especially for calculating percent crop treated, came at a time when DPR was increasing the efficiency with which it produced its annual report.

DPR was able to provide up-to-date use data and summaries to commodity groups, University of California specialists, U.S. EPA programs, and other interested parties as they developed the necessary information for the reassessment of existing tolerances.

Worker Health and Safety

Under the pesticide regulations [section 6619 of the California Code of Regulations, Title 3, Division 6, Chapter 3, Subchapter 2, Article 1], pest control operators must give farmers a written notice after every pesticide application that includes the pesticide applied, the location of the application, the date and time the application was completed, and the reentry and preharvest intervals.[2] This notice gives the farmer accurate information to help keep workers from entering fields prematurely, and also lets the farmer know the earliest date a commodity can be harvested.

DPR's Worker Health and Safety Branch also uses the data for worker exposure assessment as part of developing an overall risk characterization document. Use data help scientists estimate typical applications and how often pesticides are used.

Public Health

The expanded reporting system provides DPR, the State Department of Public Health, and the Office of Environmental Health Hazard Assessment with more complete pesticide use data for evaluating possible human illness clusters in epidemiological studies.

Endangered Species

DPR works with the county agricultural commissioners to combine site-specific use report data with geographic information system-based data on locations of endangered species. The resulting database helps commissioners resolve potential conflicts over pesticide use where endangered species may occur. DPR and the commissioners can also examine patterns of pesticide use near habitats to determine the potential impact of proposed use limitations. With location-specific data on pesticide use, restrictions on use can be better designed to protect endangered species while still allowing necessary pest control.

Water Quality

Since 1983, DPR has had a program to work with the rice industry and the Central Valley Regional Water Quality Control Board to reduce contamination of surface water by rice pesticides. Using PUR data to help in pinpointing specific agricultural practices, more precise alternative use recommendations can be made to assure protection of surface water.

The Pesticide Contamination Prevention Act requires site-specific records to help track pesticide use in areas known to be susceptible to ground water contamination.

---

[2] A reentry interval is the time from which a pesticide application is made and when workers may enter a field. A preharvest interval is the time between an application and when a commodity can be harvested.

Determinations can also be made from the records on whether a contaminated well is physically associated with agricultural practices. These records also provide data to help researchers determine why certain soil types are more prone to ground water contamination.

DPR placed certain pesticide products containing pyrethroids into reevaluation on August 31, 2006. The reevaluation is based on recent studies revealing the widespread presence of synthetic pyrethroid residues in the sediment of California waterways at levels toxic to an aquatic crustacean.

Air Quality

Many pesticide products contain volatile organic compounds (VOCs) that contribute to the formation of smog. DPR worked with the state Air Resources Board to put together a State Implementation Plan under the federal Clean Air Act to reduce emissions of all sources of VOCs, including pesticides, in nonattainment areas of the state. DPR's contribution to the plan included accurate data on the amount of VOCs contained in pesticides and the ability to inventory the use of those pesticides through pesticide use reporting.

Beginning in January 2008, regulations went into effect to reduce emissions of VOCs from fumigant pesticides. To help DPR keep track of these smog-producing emissions, PURs are used to monitor fumigant use and methods of fumigant application. This information is then used to compare with targeted emission reduction goals designed to improve air quality.

Pest Management

The Department uses the PUR database to understand patterns and changes in pest management practices. This information can be used to determine possible alternatives to pesticides that are subject to regulatory actions and to help determine possible impacts of different regulatory actions on pest management.

The PUR is used to help meet the needs of FQPA, which requires pesticide use information for determining the appropriateness of pesticide residue tolerances. As part of this process many commodity groups have created crop profiles, which include information on the pest management practices and available options, both chemical and nonchemical. Pesticide use data is critical to developing these lists of practices and options.

The PUR data have been used to support and assess grant projects for a grant program conducted by DPR to develop, demonstrate, and implement reduced-risk pest management strategies from 1995 to 2003. The grants were temporarily suspended due to the statewide budget shortfall, but funds were again available in 2007 and 2008 to offer grants. The PUR data have been used in several projects that build on work conducted in the almond and stonefruit industries. In these and other projects, the PUR data are used to address regional pesticide use patterns and environmental problems such as water and air quality. The data are also used to better understand current changes in pesticide use.

DPR has published general analyses of statewide pesticide use patterns and trends. The first analysis covered the years 1991 to 1995, and the second more detailed analysis covered 1991 to 1996. These analyses identified high-use pesticides, the crops to which those pesticides were applied, trends in use, and the pesticides most responsible for changes in use. In addition, since 1997, the annual Summary of Pesticide Use Report Data include summary trends of pesticides in several different categories such as carcinogens, reproductive toxins, and ground water contaminants.

Processor and Retailer Requirements

Food processors, produce packers, and retailers often require farmers to submit a complete history of pesticide use on crops. DPR's use report form often satisfies this requirement.

II. COMMENTS AND CLARIFICATIONS OF DATA

The following comments and points should be taken into consideration when analyzing data contained in this report:

TERMINOLOGY

The following terminology is used in this report:

Number of agricultural applications – Number of applications of pesticide products made to production agriculture. More detailed information is given below under "Number of Applications."

Pounds applied – Number of pounds of an active ingredient.

Unit type – The amount listed in this column is one of the following:

A = Acreage
C = Cubic feet (of commodity treated)
K = Thousand cubic feet (of commodity treated)
P = Pounds (of commodity treated)
S = Square feet
T = Tons (of commodity treated)
U = Miscellaneous units (e.g., number of tractors, trees, tree holes, bins, etc.)

COMMODITY CODES

DPR's pesticide product label database is used to cross-check data entries to determine if the product reported is registered for use on the reported commodity. The DPR label database uses a crop coding system based on crop names used by the U.S. EPA to prepare official label language. However, this system caused some problems until DPR modified it in the early 1990s to account for U.S. EPA's grouping of certain crops under generic names. Problems occurred when the label language in the database called a crop by one name, and the use report used another. For example, a grower may have reported a pesticide use on "almonds," but the actual label on the pesticide product--coded into the database--stated the pesticide was to be used on "nuts." DPR modified the database to eliminate records being rejected as "errors" because the specific commodity listed on the use report is not on the label. A qualifier code is appended to the commodity code in the label database to designate a commodity not specifically listed on the label as a correct use. A qualifier code would be attached to the "almond" code when nuts are only listed on the label. This system greatly reduces the number of rejections.

Plants and commodities grown in greenhouse and nursery operations represented a challenge in use reporting because of their diversity. Six commodity groupings were suggested by industry in 1990 and incorporate terminology that are generally known and accepted. The six use reporting categories are: greenhouse-grown cut flowers or greens; outdoor-grown cut flowers or greens; greenhouse-grown plants in containers; outdoor-grown plants in container/field-grown plants; greenhouse-grown transplants/propagative material; and outdoor-grown transplants/propagative material.

Tomatoes and grapes were also separated into two categories because of public and processor interest in differentiating pesticide use. Tomatoes are assigned two codes to differentiate between fresh market and processing categories. One code was assigned to table grapes, which includes grapes grown for fresh market, raisins, canning, or juicing. A second code was assigned to wine grapes.

UNREGISTERED USE

The report contains entries that reflect the use of a pesticide on a commodity for which the pesticide is not currently registered. This sometimes occurs because the original use report was in error, that is, either the pesticide or the commodity was inaccurately reported. DPR's computer program checks that the commodity is listed on the label, but nonetheless such errors appear in the PUR, possibly because of errors in the label database. Also, the validation program does not check whether the pesticide product was registered at the time of application. For example, parathion (ethyl parathion) is shown reported on crops after most uses were suspended in 1992. (These records are researched and corrected as time and resources allow.) DPR continues to implement methods that identify and reduce these types of reporting errors in future reports. Other instances may occur because by law, growers are sometimes allowed to use stock they have on hand of a pesticide product that has been withdrawn from the market by the manufacturer or suspended or canceled by regulatory authorities.

Other reporting "errors" may occur when a pesticide is applied directly to a site to control a particular pest, but is not applied directly to the crop in the field. A grower may use an herbicide to treat weeds on the edge of a field, a fumigant on bare soil prior to planting, or a rodenticide to treat rodent burrows. For example, reporting the use of the herbicide glyphosate on tomatoes – when it was actually applied to bare soil prior to planting the tomatoes – could be perceived to be an error. Although technically incorrect, recording the data as if the application were made directly to the commodity provides valuable crop usage information for DPR's regulatory program.

ADJUVANTS

Data on spray adjuvants (including emulsifiers, wetting agents, foam suppressants, and other efficacy enhancers), not reported prior to full use reporting, are now included. Examples of these types of chemicals include the "alkyls" and some petroleum distillates. (Adjuvants are exempt from federal registration requirements, but must be registered as pesticides in California.)

ZERO POUNDS APPLIED

There are a few entries in this report in which the total pounds applied for certain active ingredients are displayed as zero. This is because the chemical (active ingredient) made up a very small percentage of the formulated product that was used. When these products are applied in extremely low quantities, the resulting value of the active ingredient is too low to register an amount.

ACRES TREATED

The summary information in this annual report cannot be used to determine the total number of acres of a crop. However, it can be used to determine the cumulative acres treated. The problem is that the same field can be treated more than once in a year with the same active ingredient. A similar problem occurs when the product used contains more than one active ingredient. (In any pesticide product, the active ingredient is the component that kills, or otherwise controls, target pests. A pesticide product is made up of one or more active ingredients, as well as one or more inert ingredients.) For example, if a 20-acre field is treated with a product that contains three different pesticide active ingredients, a use report is filed by the farmer correctly recording the application of a single pesticide product to 20 acres. However, in the summary tables, the three different active ingredients will each have recorded 20 acres treated. Adding these values results in a total of 60 acres as being treated instead of the 20 acres actually treated.

NUMBER OF APPLICATIONS

The values for number of applications include only production agricultural applications. Applicators are required to submit one of two basic types of use reports, a production agricultural report or a monthly summary report. The production agricultural report must include information for each application. The monthly summary report, for all uses other than production agriculture, includes only monthly totals for all applications of pesticide product, site or commodity, and applicator. The total number of applications in the monthly summary reports is not consistently given so they are no longer included in the totals. In the annual PUR reports before 1997, each monthly summary record was counted as one application.

In the annual summary report by commodity, the total number of applications given for each commodity may not equal the sum of all applications of each active ingredient on that commodity. As explained above, some pesticide products contain more than one active ingredient. If the number of applications were summed for each active ingredient in such a product, the total number of applications would be more than one, even though only one application of the product was made.

ERRORS

In any database with millions of records there will almost certainly be errors. Most of the values in the PUR are checked for errors and where possible corrections are made. However, some errors will remain. If a value is completely unknown the value will either be left blank for numeric fields or replaced with a “?” or “UNKNOWN” in character fields.

If a reported rate of use (pounds of pesticide per area treated) was so large it was probably in error, the rate was replaced with an estimated rate equal to the median rate of all applications of the pesticide product on the same crop or other site treated. Since the error could have been in the pounds reported or the area or unit treated, the value that was most unusual was the one replaced with an estimate. In some cases, a reasonable estimate could not be made, for example, if there were no or few other reported

applications of the product on the site. In these cases, the pounds value was set equal to 0.

Pesticide rates were considered outliers if (1) they were higher than 200 pounds of active ingredient per acre (or greater than 1,000 pounds per acre for fumigants); (2) they were 50 times larger than the median rate for all uses with the same pesticide product, crop treated, unit treated, and record type (that is, production agricultural or all other uses); or (3) they were higher than a value determined by a neural network procedure that approximates what a group of 12 scientists believed were obvious outliers. Although these criteria identified as outliers less than one percent of the rate values in the PUR, some rates were so large that if included in the sums, they would have significantly affected total pounds applied of some pesticides.

III. DATA SUMMARY

This report is a summary of data submitted to DPR. Total pounds may change slightly due to ongoing error correction. The revised numbers, when available, will more accurately reflect the total pounds applied.

PESTICIDE USE IN CALIFORNIA

In 2007, there were 172,163,465 pounds of pesticide active ingredients reported used in California. Annual use has varied from year to year since full use reporting was implemented in 1990. For example, reported pesticide use was 190 million pounds in 2006, 195 million pounds in 2005, and 180 million pounds in 2004.

Such variances are, and will continue to be, a normal occurrence. These fluctuations can be attributed to a variety of factors, including changes in planted acreage, crop plantings, pest pressures, and weather conditions. For example, extremely heavy rains result in excessive weeds, thus more pesticides may be used; drought conditions may result in fewer planted acres, thus less pesticide may be used.

As in previous years, the greatest pesticide use occurred in California's San Joaquin Valley (Table 1). Four counties in this region had the highest use: Fresno, Kern, Tulare, and San Joaquin.

Table 2 breaks down the pounds of pesticide use by general use categories: production agriculture, post-harvest commodity fumigation, structural pest control, landscape maintenance, and all others.

PESTICIDE SALES IN CALIFORNIA

Reported pesticide applications are only a portion of the pesticides sold each year. Typically, about two-thirds of the pesticide active ingredients sold in a given year are not subject to use reporting. Examples of non-reported active ingredients are chlorine (used primarily for municipal water treatment) and home-use pesticide products.

There were 679 million pounds sold in 2007, 743 million pounds sold in 2006, 611 million pounds sold in 2005, and 667 million pounds in 2004. Prior years data are posted on DPR's web site at www.cdpr.ca.gov; click "A – Z Index", "Sales of pesticides".

In addition, it should be noted that the pounds of pesticides used and the number of applications are not necessarily accurate indicators of the extent of pesticide use or, conversely, the extent of use of reduced-risk pest management methods. For example, farmers may make a number of small-scale "spot" applications targeted at problem areas rather than one treatment of a large area. They may replace a more toxic pesticide used at one pound per acre with a less hazardous compound that must be applied at several pounds per acre. Either of these scenarios could increase the number of applications or

amount of pounds used, respectively, without indicating an increased reliance on pesticides.

Table 1. Total pounds of pesticide active ingredients reported in each county and rank during 2006 and 2007.

* This category includes pesticide applications reported in the following general categories: pest control on rights-of-way; public health which includes mosquito abatement work; vertebrate pest control; fumigation of nonfood and nonfeed materials such as lumber, furniture, etc.; pesticide used in research; and regulatory pest control used in ongoing control and/eradication of pest infestations.

IV. TRENDS IN USE IN CERTAIN PESTICIDE CATEGORIES

Reported pesticide use in California in 2007 totaled 172 million pounds, a decrease of nearly 16 million pounds from 2006. Production agriculture, the major category of use subject to reporting requirements, accounted for most of the overall decrease in use. Applications decreased by 11 million pounds for production agriculture. Similarly, there was a 1.3 million pound decrease in structural pest control, a decrease of 0.6 million pounds in landscape maintenance, and a 3 million pound decrease of other reported non-agricultural use. However, there was an increase of 0.2 million pounds in post-harvest treatments.

The active ingredients (AI) with the largest uses by pounds in 2007 were sulfur, petroleum and mineral oils, metam-sodium, 1,3-dichloropropene (1,3-D), glyphosate, and copper compounds. Sulfur was the most highly used non-adjuvant pesticide in 2007, both in pounds applied and acres treated. By pounds, sulfur accounted for 27 percent of all reported pesticide use. Sulfur is a natural fungicide favored by both conventional and organic farmers.

Most of the decline in all reported pesticide use was from petroleum and mineral oils, which decreased by 4.3 million pounds (13 percent). Other non-adjuvant pesticides that declined in use include copper fungicides (2.8 million pound decrease, 29 percent), metam-sodium (1.5 million pound decrease, 13 percent), sulfuryl fluoride (730,000 pound decrease, 25 percent), chromic acid (650,000 pound decrease, 98 percent), and glyphosate (570,000 pound decrease, 7 percent).

In contrast, some pesticide use increased. Non-adjuvant pesticides with the greatest increase in pounds applied were 1,3-D (860,000 pound increase, 10 percent), potassium n-methyldithiocarbamate (metam-potassium) (583,000 pound increase, 18 percent) and chloropicrin (459,000 pound increase, 9.1 percent).

Major crops or sites that showed an overall increase in pesticide pounds applied from 2006 to 2007 included wine grapes (2.6 million pounds increase), lumber treatment (978,000 pounds increase), pre-plant soil fumigations (586,000 pounds), and walnut (437,000 pounds). Major crops or sites with decreased pounds applied included fumigation of nonfood and nonfeed materials (3.7 million pounds decrease), cotton (2.1 million pounds), orange (2.0 million pounds), pistachio (1.8 million pounds), almond (1.7 million pounds), peach/nectarine (1.6 million pounds), processing tomatoes (1.6 million pounds), structural pest control (1.3 million pounds), and raisin and table grapes (1.1 million pounds).

DPR data analyses have shown that pesticide use varies from year to year depending upon pest problems, weather, acreage and types of crops planted, economics, and other factors. Of the different AI types, insecticides had the greatest decrease by pounds. Fungicides (other than sulfur) had the next largest decrease by pounds and the largest decrease by acres treated. Herbicide use decreased by pounds and acres treated.

Conversely, pounds of fumigants decreased but acres treated with fumigants slightly increased.

Pesticide use is reported as the number of pounds of AI and the total number of acres treated. The data for pounds include both agricultural and nonagricultural applications; the data for acres treated are primarily agricultural applications. The number of acres treated means the cumulative number of acres treated; the acres treated in each application are summed even when the same field is sprayed more than once in a year. (For example, if one acre is treated three times in a season with an individual AI, it is counted as three acres treated in the tables and graphs in Sections IV and V of this report.)

To provide an overview, pesticide use is summarized for eight different pesticide categories from 1997 to 2007 (Tables 3–10) and from 1994 to 2007 (Figures 1–8). These categories classify pesticides according to certain characteristics such as reproductive toxins, carcinogens, or reduced-risk characteristics. Use of most pesticide categories decreased from 2006 to 2007, except for increases in pounds of biopesticides and acres treated with oils or fumigants. Some of the major changes from 2006 to 2007 include:

- Chemicals classified as reproductive toxins decreased in pounds applied from 2006 to 2007 (down 1.9 million pounds or 10 percent) and decreased in acres treated (down 130,000 acres or 7.2 percent). The decrease in pounds was mostly from decreases in the fumigant metam-sodium and the decrease in acres was mostly from decreases in the fungicide myclobutanil. The pesticides in this category are ones listed on the State's Proposition 65 list of chemicals "known to cause reproductive toxicity."

- Use of chemicals classified as carcinogens decreased from 2006 to 2007 (down 2.7 million pounds or 10 percent and down 547,000 acres or 15 percent). The decrease in pounds was mainly due to a decrease in use of the fumigant metam-sodium and the fungicide/insecticide chromic acid. The decrease in acres treated was mostly from decreases in the herbicide diuron and fungicide mancozeb. The pesticides in this category are ones listed by U.S. EPA as B2 carcinogens or on the State's Proposition 65 list of chemicals "known to cause cancer".

- Use of cholinesterase-inhibiting pesticides (organophosphate (OP) and carbamate pesticides), which include compounds of high regulatory concern, continued to decline as they have for nearly every year since 1995. Use decreased form 2006 to 2007 both in pounds (down 1.1 million or 16 percent) and in acres treated (down 756,000 acres or 13 percent). The AIs with the greatest decreases in pounds were chlorpyrifos, phosmet and ethephon; the AIs with the greatest decreases in acres treated were chlorpyrifos, ethephon, and oxamyl. Use of most OPs and carbamates decreased; however, use of propamocarb hydrochloride (fungicide), malathion (insecticide) and EPTC (herbicide) increased.

- Use of all chemicals categorized as ground water contaminants decreased by pounds (down 303,000 pounds or 16 percent), and by acres treated (down 275,000 acres or 18 percent) in 2007 compared to 2006. The decreases in pounds and acres treated were mostly from decreases in the herbicides diuron and simazine. The use of most ground water contaminating pesticides decreased. However, both pounds and acres treated with the herbicides bromacil and bentazon increased.

- Chemicals categorized as toxic air contaminants, another group of pesticides of regulatory concern, decreased from 2006 to 2007 both in pounds (down 2.5 million pounds or 6.3 percent) and by acres treated (down 452,000 acres or 12 percent). By pounds, most toxic air contaminants are fumigants, which are used at high rates. By acres treated, the main decreasing AIs were the fungicides mancozeb and captan, and the herbicide trifluralin.

- Fumigant chemicals decreased in pounds applied from 2006 to 2007 (down 294,000 pounds or 0.8 percent) but marginally increased in cumulative acres treated (up 1,235 acres or 0.3 percent). Pounds of 3 of the 6 major fumigants decreased (metam-sodium, sulfuryl fluoride, and methyl bromide) and pounds of 3 fumigants increased (1,3-D, potassium n-methyldithiocarbamate, and chloropicrin). By acres treated, use of all major fumigants increased except for metam-sodium and methyl bromide.

- Pounds of oil pesticides decreased (down 4.3 million pounds or 13 percent) but increased by acres treated (up 118,000 acres or 3.7 percent). Oils include many different chemicals, but the category used here includes only ones derived from petroleum distillation. Some of these oils may be on the State's Proposition 65 list of chemicals "known to cause cancer" but most serve as alternatives to highly toxic pesticides. Oils are also used by organic growers.

- Biopesticide use decreased by pounds (down 173,000 pounds or 20 percent) and decreased by acres treated (down 153,000 acres or 6.5 percent) from 2006 to 2007. The most used biopesticide by pounds was *Bacillus thuringiensis* (*Bt*)(combining all subspecies) and the most used by acres treated was propylene glycol followed closely by *Bt* and gibberellins. *Bt* also had the largest increase by pounds. The AIs with the largest decrease in pounds were soybean oil and potassium bicarbonate. The AIs with the greatest decreases in acres treated were propylene glycol, gamma aminobutyric acid, and glutamic acid. AIs with the greatest increase in acres treated were azadirachtin and s-methoprene. Biopesticides include microorganisms and naturally occurring compounds, or compounds essentially identical to naturally occurring compounds not toxic to the target pest (such as pheromones).

Since 1993, the reported pounds of pesticides applied have fluctuated from year to year. An increase or decrease in use from one year to the next or in the span of a few years does not necessarily indicate a general trend in use; it simply may reflect variations related to various factors (e.g. climate or economic changes). Short periods of time (three

to five years) may suggest trends, such as the increased pesticide use from 2001 to 2005 or the decreased use from 1998 to 2001. However, regression analyses on use from 1993 to 2007 do not indicate a significant trend of either increase or decrease in total pesticide use.

To improve data quality when calculating the total pounds of pesticides, DPR excluded values that were so large they were probably in error. The procedure to exclude probable errors involved the development of complex error-checking algorithms, a data improvement process that is ongoing.

Over-reporting errors have a much greater impact on the numerical accuracy of the database than under-reporting errors. For example, if a field is treated with 100 pounds of a pesticide AI and the application is erroneously recorded as 100,000 pounds (a decimal point shift of three places to the right), an error of 99,900 pounds is introduced into the database. If the same degree of error is made in shifting the decimal point to the left, the application is recorded as 0.1 pound, and an error of 99.9 pounds is entered into the database.

The summaries detailed in the following use categories are not intended to serve as indicators of pesticide risks to the public or the environment. Rather, the data supports DPR regulatory functions to enhance public safety and environmental protection. (See “How Pesticide Data are Used” on page 2.)

USE TRENDS OF PESTICIDES ON THE STATE'S PROPOSITION 65 LIST OF CHEMICALS THAT ARE "KNOWN TO CAUSE REPRODUCTIVE TOXICITY"

Table 3A. *The reported pounds of pesticides used which are on the State's Proposition 65 list of chemicals that are "known to cause reproductive toxicity." Use includes both agricultural and reportable non-agricultural applications. Data are from the Department of Pesticide Regulation's Pesticide Use Reports.*

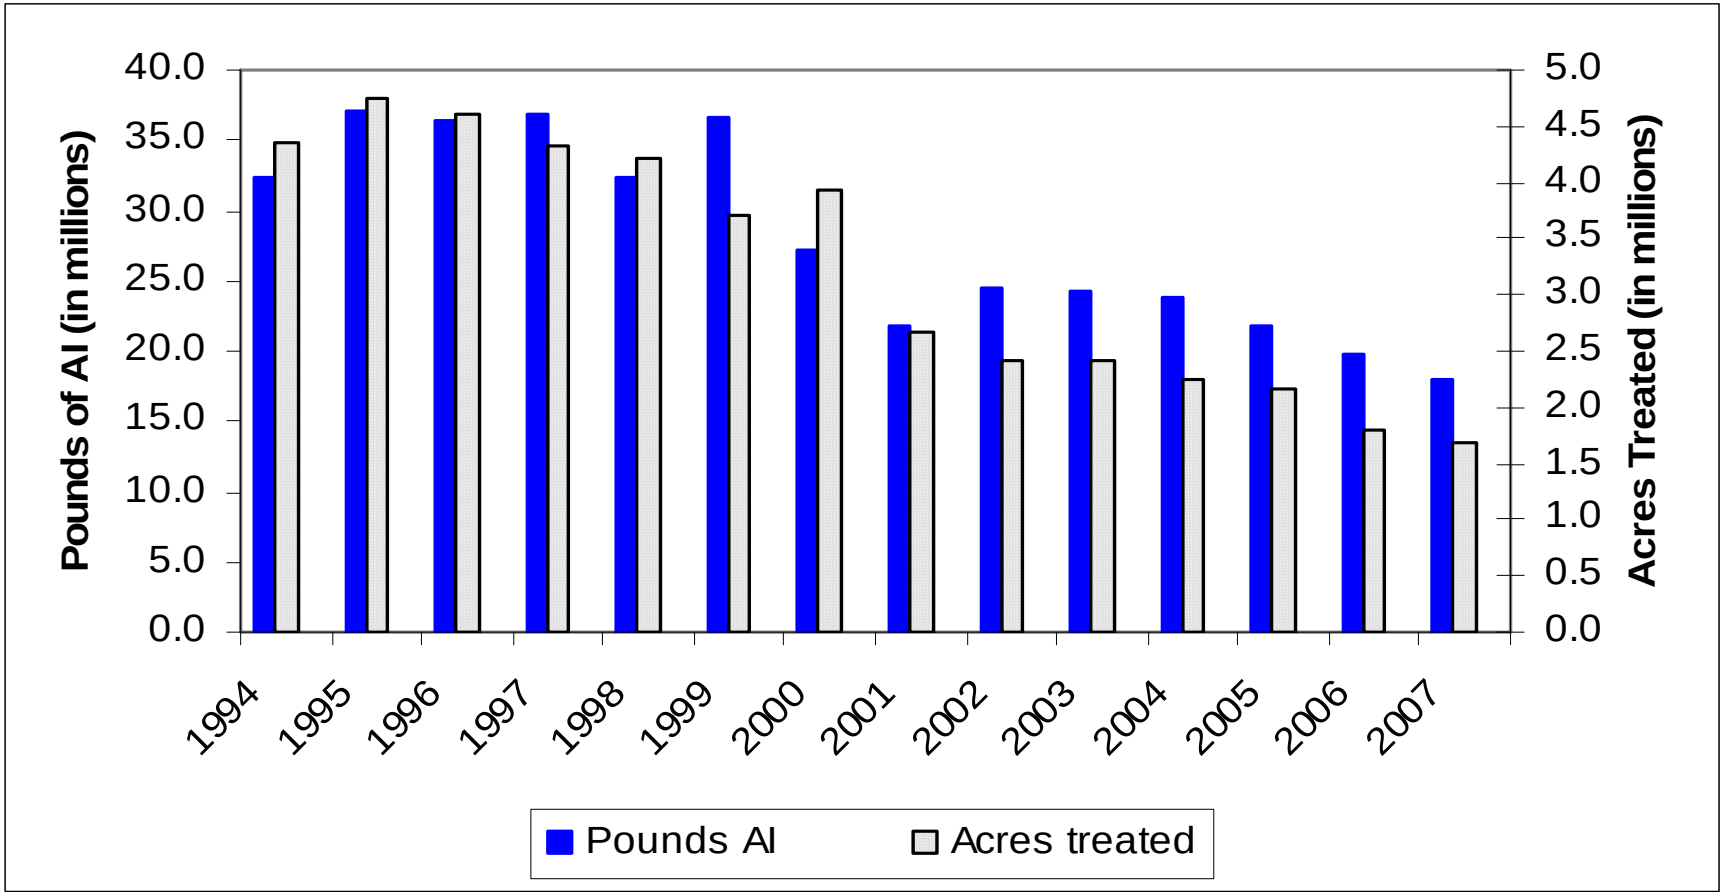
Figure 1. *Use trends of pesticides that are on the State's Proposition 65 list of chemicals that are "known to cause reproductive toxicity." Reported pounds of active ingredient (AI) applied include both agricultural and non-agricultural applications. The reported cumulative acres treated include primarily agricultural applications. Data are from the Department of Pesticide Regulation's Pesticide Use Reports.*



USE TRENDS OF PESTICIDES LISTED BY U.S. EPA AS CARCINOGENS OR BY THE STATE AS "KNOWN TO CAUSE CANCER"

Table 4A. *The reported pounds of pesticides used that are listed by U.S. EPA as B2 carcinogens or that are on the State's Proposition 65 list of chemicals "known to cause cancer." Use includes both agricultural and reportable non-agricultural applications. Data are from the Department of Pesticide Regulation's Pesticide Use Reports.*

Table 4B. *The reported cumulative acres treated with pesticides listed by U.S. EPA as B2 carcinogens or on the State's Proposition 65 list of chemicals "known to cause cancer." Use includes primarily agricultural applications. The grand total for acres treated is less than the sum of acres treated for all active ingredients because some products contain more than one active ingredient. Data are from the Department of Pesticide Regulation's Pesticide Use.*

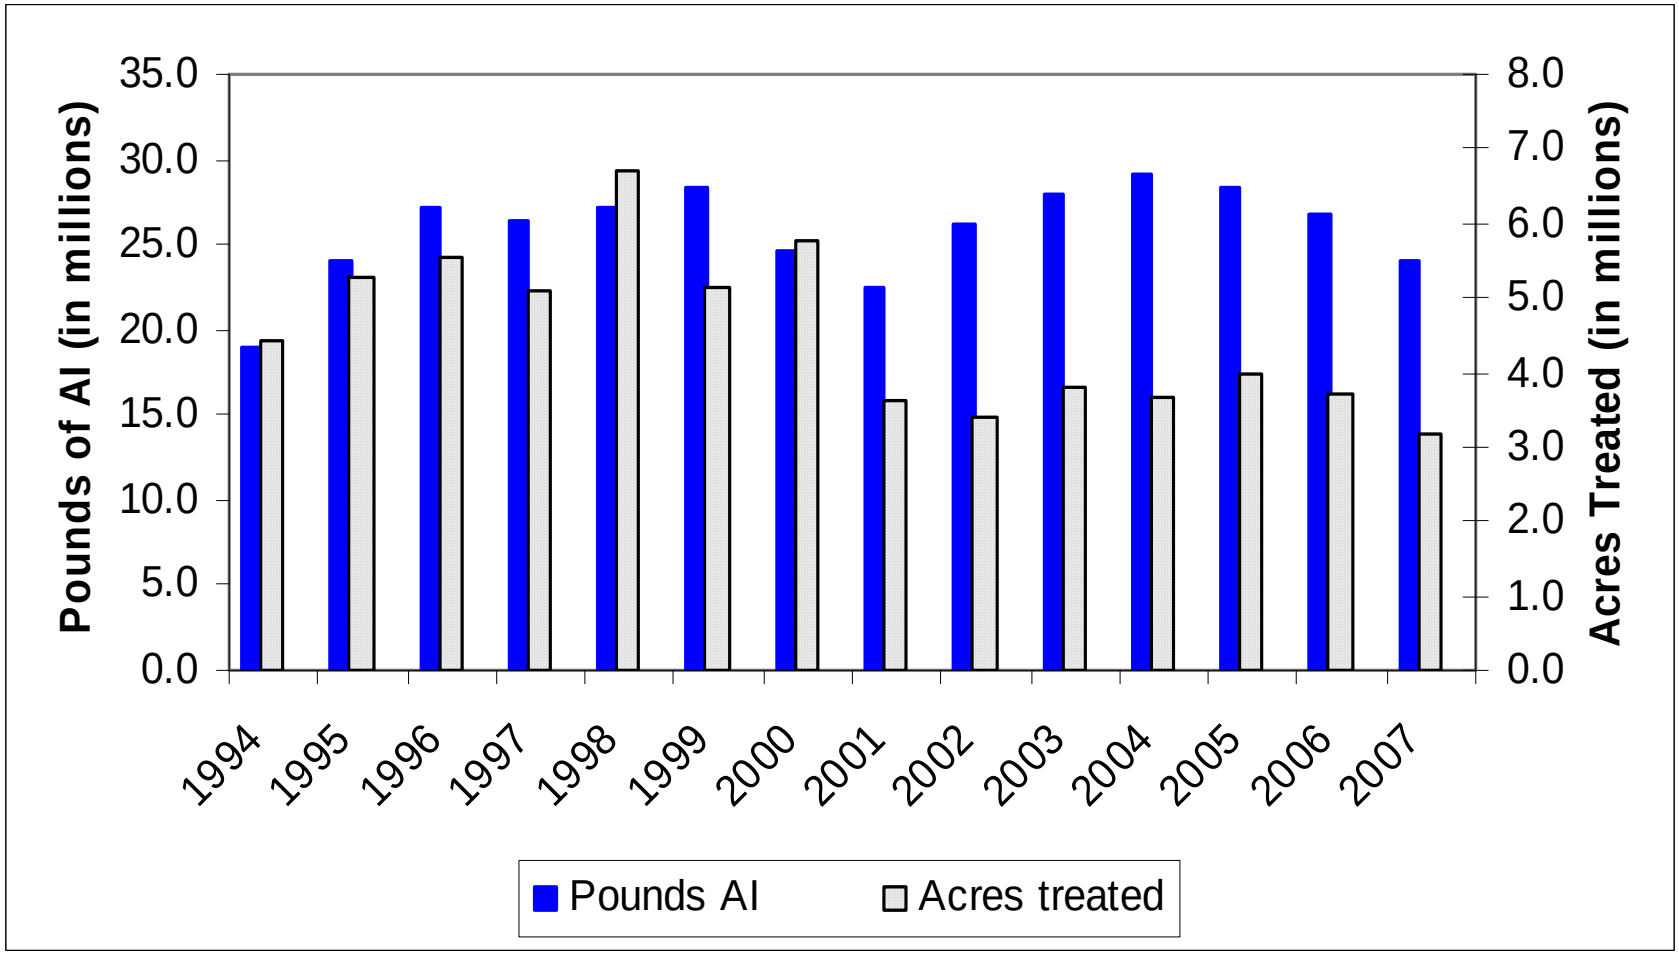
Figure 2. *Use trends of pesticides that are listed by U.S. EPA as B2 carcinogens or that are on the State's Proposition 65 list of chemicals "known to cause cancer." Reported pounds of active ingredient (AI) applied include both agricultural and reportable non-agricultural applications. The reported cumulative acres treated include primarily agricultural applications. Data are from the Department of Pesticide Regulation's Pesticide Use Reports.*



USE TRENDS OF CHOLINESTERASE-INHIBITING PESTICIDES

Table 5A. *The reported pounds of cholinesterase-inhibiting pesticides used. These pesticides are organophosphate and carbamate active ingredients. Use includes both agricultural and reportable non-agricultural applications. Data are from the Department of Pesticide Regulation's Pesticide Use Reports.*

Table 7B. *The reported cumulative acres treated in California with pesticides on DPR's toxic air contaminants list. These pesticides are the active ingredients listed in the California Code of Regulations, Title 3, Division 6, Chapter 4, Subchapter 1, Article 1, Section 6860. Use includes primarily agricultural applications. The grand total for acres treated is less than the sum of acres treated for all active ingredients because some products contain more than one active ingredient. Data are from the Department of Pesticide Regulation's Pesticide Use Reports.*

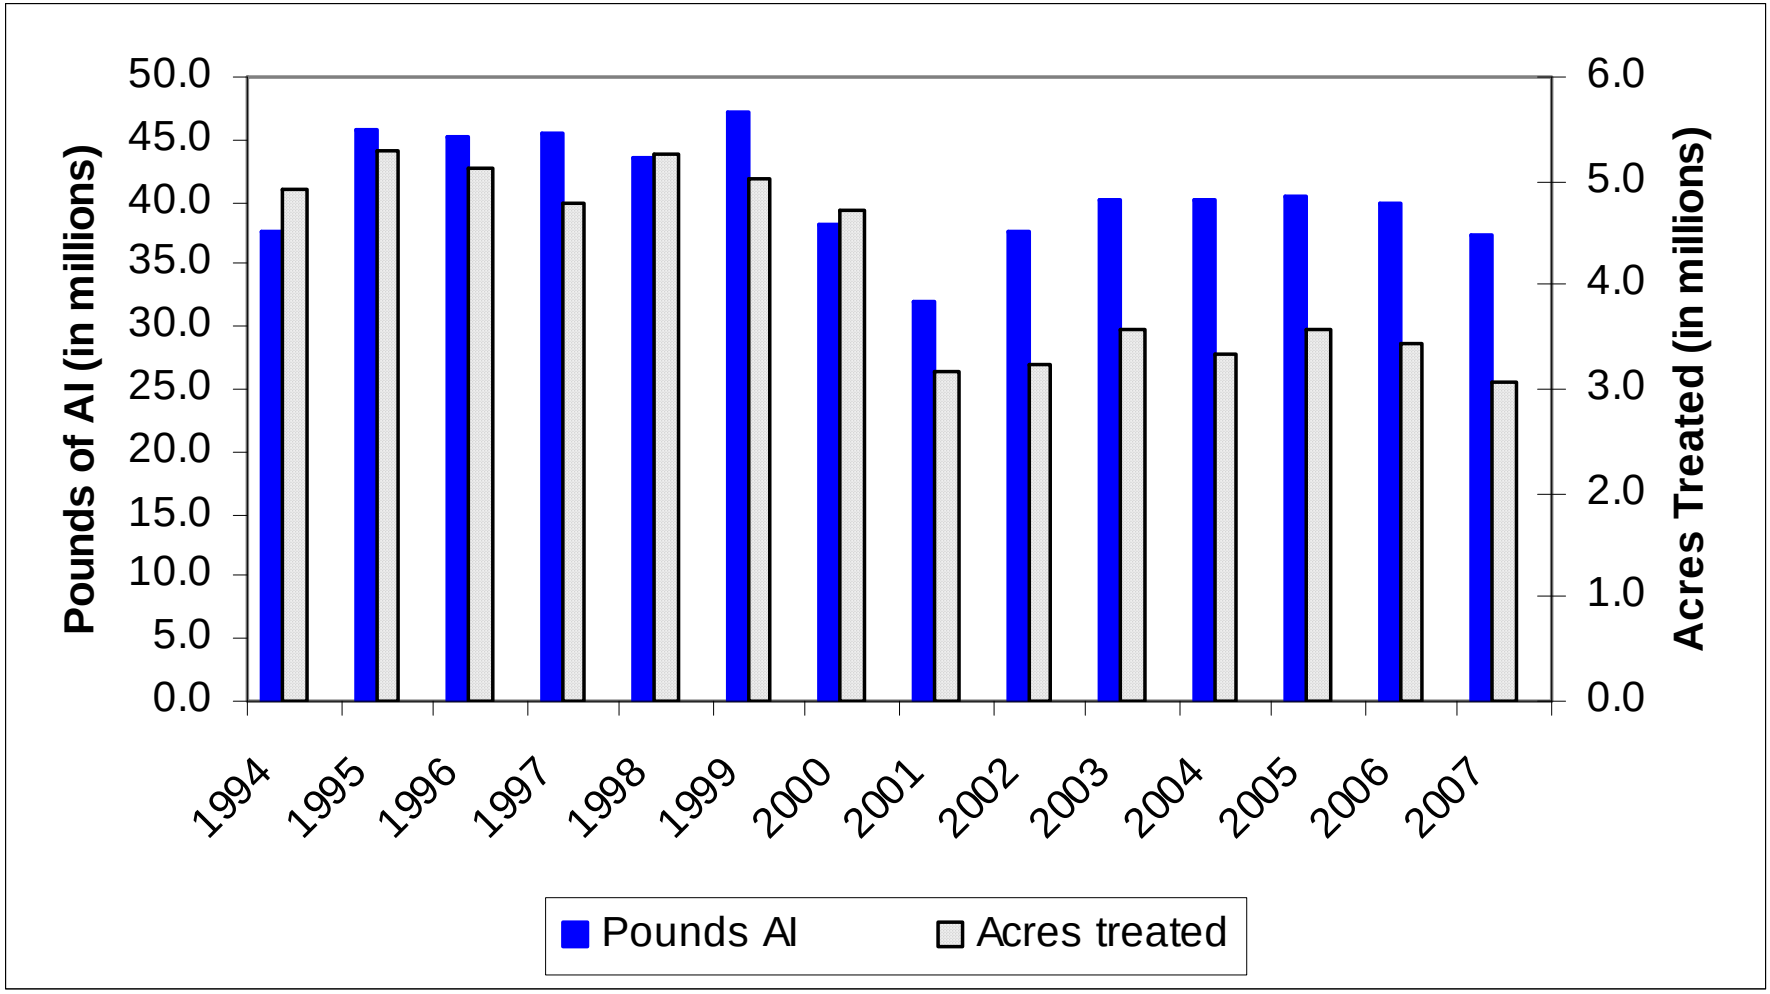
Figure 5. *Use trends of pesticides on DPR's toxic air contaminants list. These pesticides are the active ingredients listed in the California Code of Regulations, Title 3, Division 6, Chapter 4, Subchapter 1, Article 1, Section 6860. Reported pounds of active ingredient (AI) applied include both agricultural and reportable non-agricultural applications. The reported cumulative acres treated include primarily agricultural applications. Data are from the Department of Pesticide Regulation's Pesticide Use Reports.*



USE TRENDS OF FUMIGANT PESTICIDES

Table 8A. *The reported pounds of fumigant pesticides used. Use includes both agricultural and reportable non-agricultural applications. Data are from the Department of Pesticide Regulation's Pesticide Use Reports.*

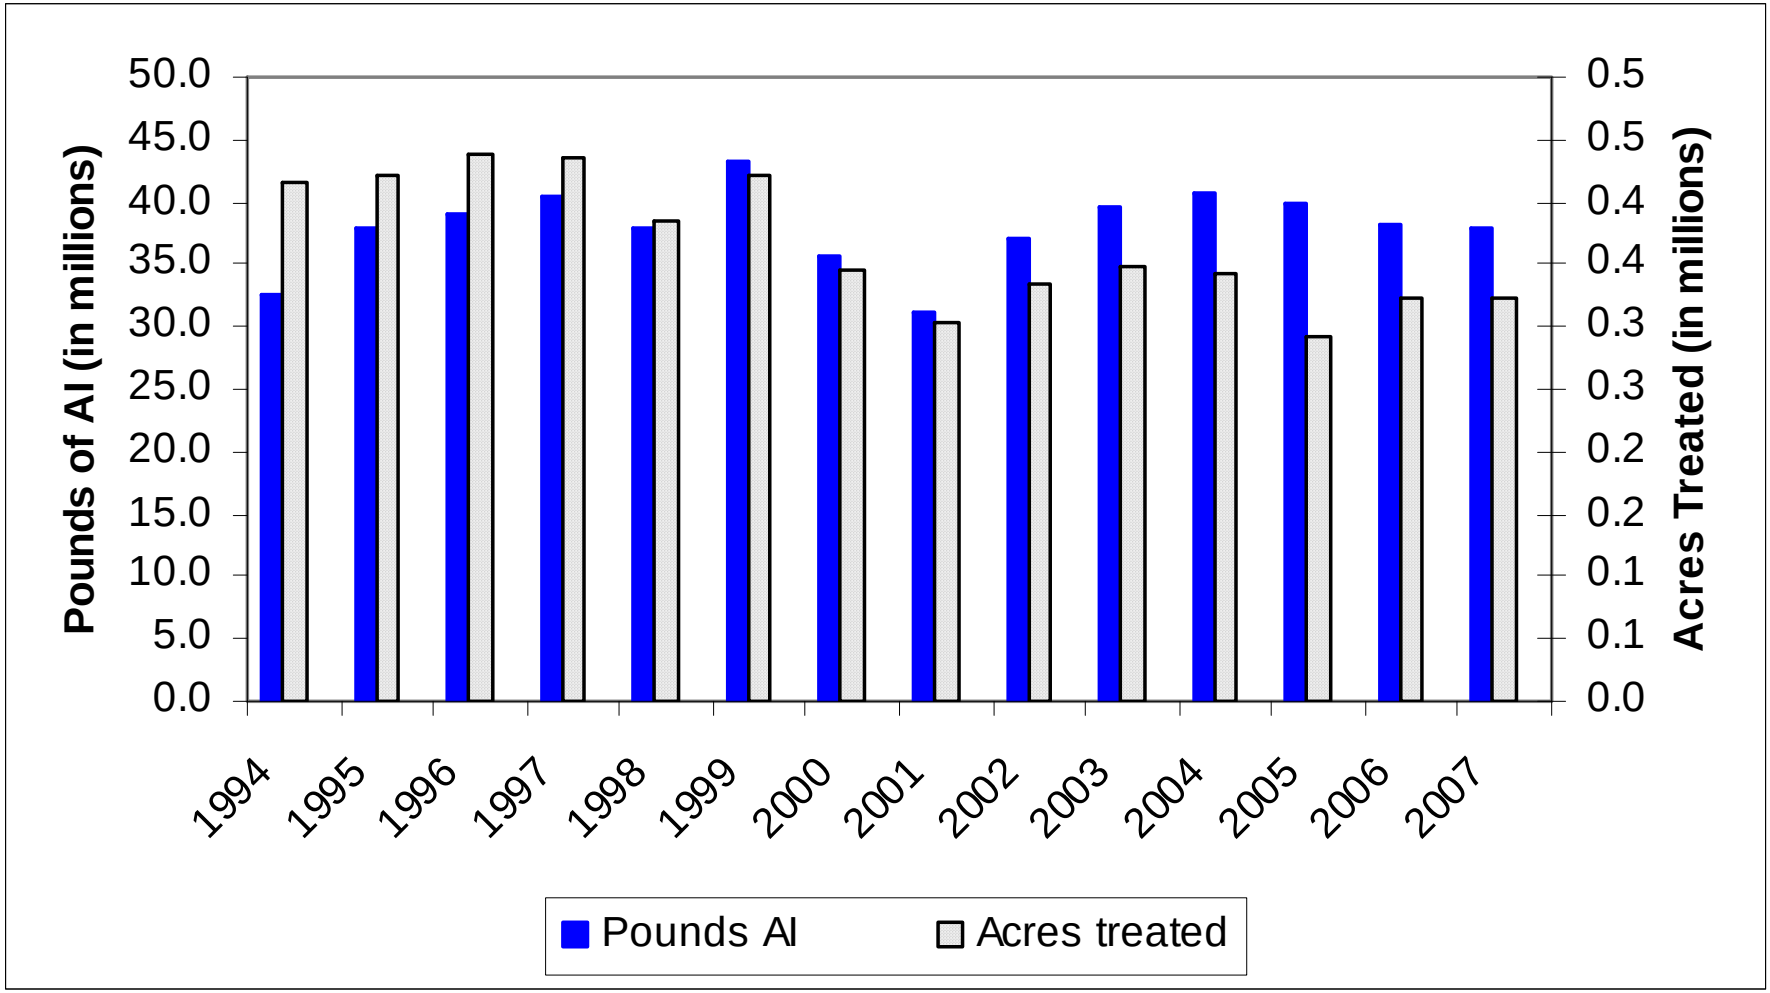
Figure 6. *Use trends of fumigant pesticides. Reported pounds of active ingredient (AI) applied include both agricultural and reportable non-agricultural applications. The reported cumulative acres treated include primarily agricultural applications. Data are from the Department of Pesticide Regulation's Pesticide Use Reports.*



USE TRENDS OF OIL PESTICIDES

Table 9A. *The reported pounds of oil pesticides. As a broad group, oil pesticides and other petroleum distillates are on U.S. EPA's list of B2 carcinogens or the State's Proposition 65 list of chemicals "known to cause cancer." However, these classifications do not distinguish among oil pesticides that may not qualify as carcinogenic due to their degree of refinement. Many such oil pesticides also serve as alternatives to high-toxicity chemicals. For this reason, oil pesticide data was classified separately in this report. Use includes both agricultural and reportable non-agricultural applications. Data are from the Department of Pesticide Regulation's Pesticide Use Reports.*

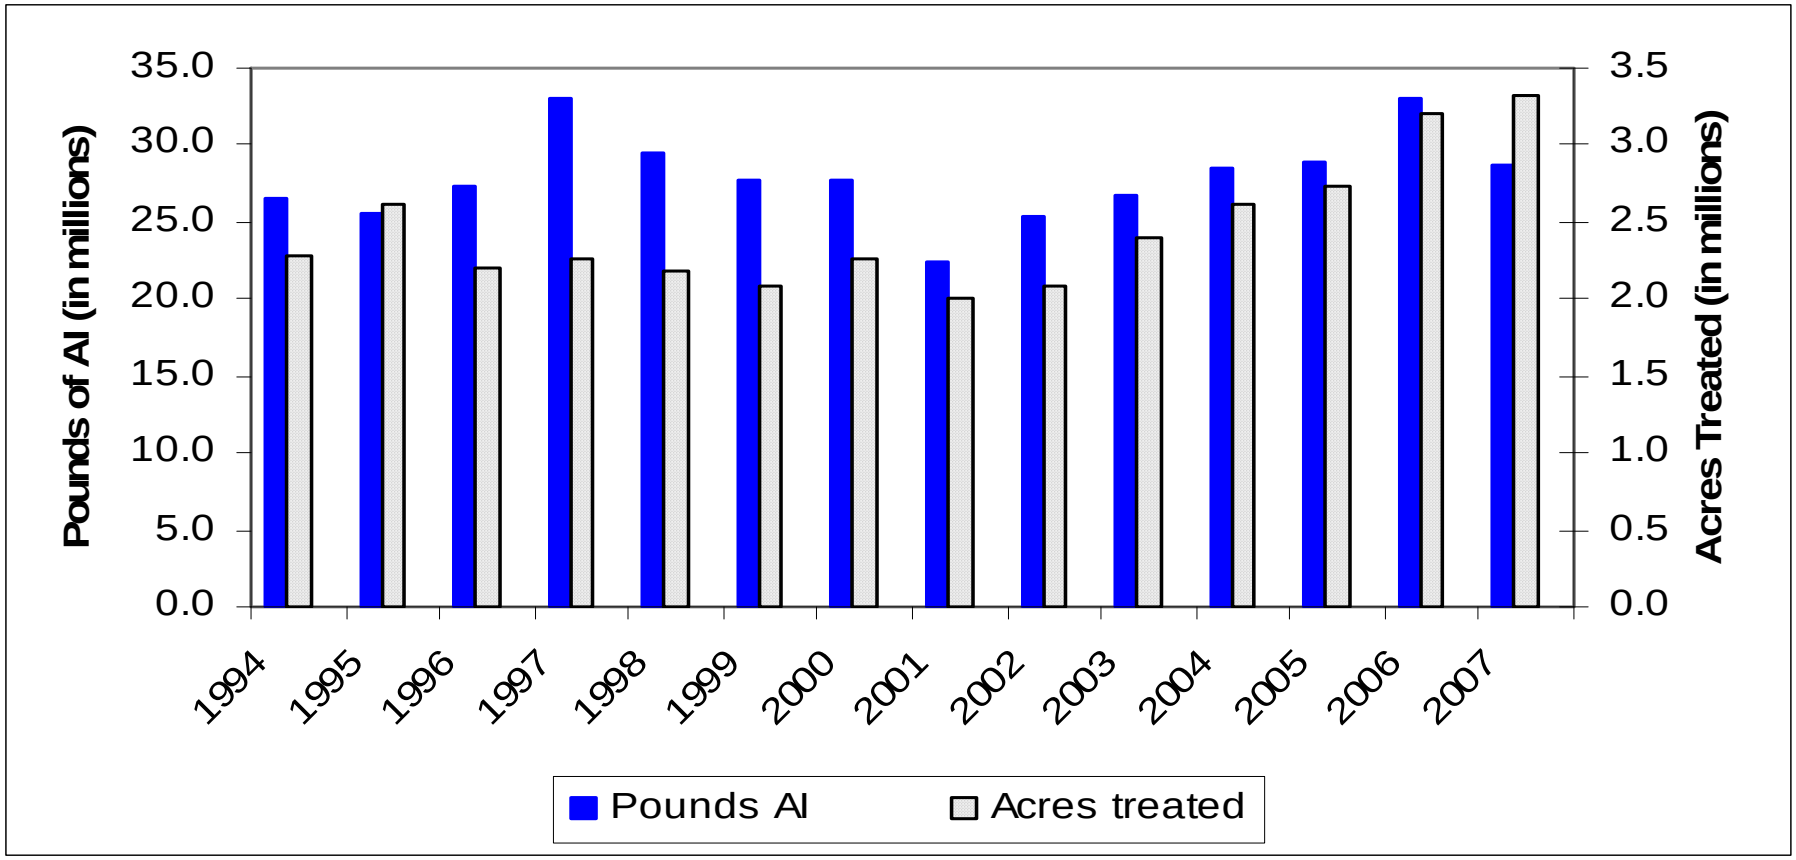
Figure 7. *Use trends of oil pesticides. As a broad group, oil pesticides and other petroleum distillates are on U.S. EPA's list of B2 carcinogens or the State's Proposition 65 list of chemicals "known to cause cancer." However, these classifications do not distinguish among oil pesticides that may not qualify as carcinogenic due to their degree of refinement. Many such oil pesticides also serve as alternatives to high-toxicity chemicals. For this reason, oil pesticide data was classified separately in this report. Reported pounds of active ingredient (AI) applied include both agricultural and reportable non-agricultural applications. The reported cumulative acres treated include primarily agricultural applications. Data are from the Department of Pesticide Regulation's Pesticide Use Reports.*



USE TRENDS OF BIOPESTICIDES

Table 10A. *The reported pounds of biopesticides applied in California. Biopesticides include microorganisms and naturally occurring compounds, or compounds essentially identical to naturally occurring compounds that are not toxic to the target pest (such as pheromones). Use includes both agricultural and non-agricultural applications. Zero values in early years likely indicate the pesticide was not yet registered for use. Data are from the Department of Pesticide Regulation's Pesticide Use Reports.*

Table 10B. *The reported cumulative acres treated in California with each biopesticide. Biopesticides includes microorganisms and naturally occurring compounds, or compounds essentially identical to naturally occurring compounds that are not toxic to the target pest (such as pheromones). Use includes primarily agricultural applications. The grand total for acres treated is less than the sum of acres for all active ingredients because some products contain more than one active ingredient. Zero values in early years likely indicate the pesticide was not yet registered for use. Data are from the Department of Pesticide Regulation's Pesticide Use Reports.*

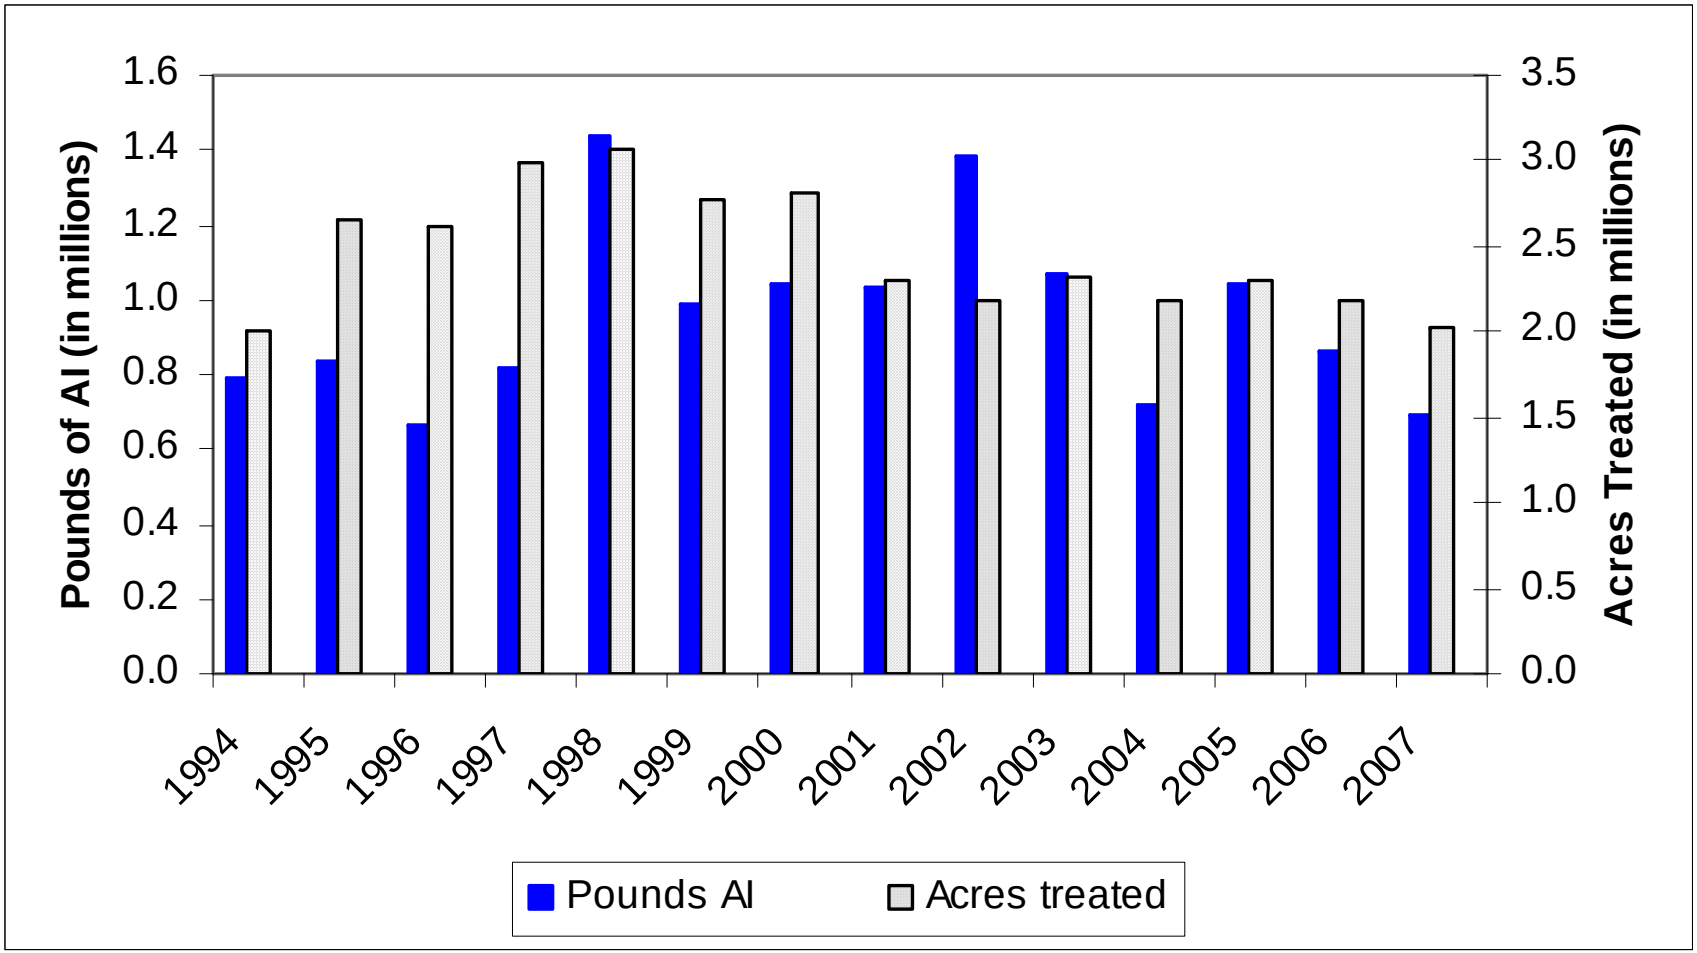
Figure 8. *Use trends of biopesticides. Biopesticides include microorganisms and naturally occurring compounds, or compounds essentially identical to naturally occurring compounds that are not toxic to the target pest (such as pheromones). Reported pounds of active ingredient (AI) applied include both agricultural and reportable non-agricultural applications. The reported cumulative acres treated include primarily agricultural applications. Data are from the Department of Pesticide Regulation's Pesticide Use Reports.*



V. TRENDS IN PESTICIDE USE IN CERTAIN COMMODITIES

This summary describes possible reasons for changes in pesticide use from 2006 to 2007 for the following commodities: (1) almonds, (2) wine grapes, (3) cotton, (4) table and raisin grapes, (5) alfalfa, (6) processing tomatoes, (7) oranges, (8) rice, (9) head lettuce, (10) peaches and nectarines, (11) strawberries, and (12) carrots. These 12 commodities were chosen because each were treated with more than 5 million pounds of active ingredients (AIs) or cumulatively treated on more than 2 million acres. Collectively, this represents 68 percent of all reported pesticide pounds used (75 percent of all pounds used on agricultural fields) and 70 percent of the acres treated in 2007.

Information used to develop this section was drawn from several publications and phone interviews with pest control advisors, growers, University of California Cooperative Extension farm advisors and specialists, researchers, and commodity association representatives. DPR staff analyzed the information, using their knowledge of pesticides, California agriculture, pests, and pest management practices to draw conclusions about possible explanations for changes in pesticide use. However, it is important to note these explanations are based on anecdotal information, not rigorous statistical analyses.

Reported pesticide use in California in 2007 totaled 172 million pounds, a decrease of 16 million pounds from 2006 (8.4 percent). The AIs with the largest uses by pounds were sulfur, petroleum and mineral oils, metam-sodium, 1,3-dichloropropene (1,3-D), and glyphosate. By pounds, sulfur accounted for 27 percent of all reported pesticide use in 2007. Sulfur use was close to that in 2006, with only a 0.2 percent decrease. Sulfur is a natural fungicide favored by both conventional and organic farmers and is used mostly to control powdery mildew on grapes. The pesticide that accounted for most of the decrease in pounds applied was oil, which decreased by 4.3 million pounds (13 percent). Other pesticides that declined in use include copper fungicides (2.8 million pound decrease, 29 percent), the fumigant metam-sodium (1.5 million pound decrease, 13 percent), the fumigant sulfuryl fluoride (730,000 pound decrease, 25 percent), the wood preservative chromic acid (650,000 pound decrease, 98 percent), and the herbicide glyphosate (570,000 pound decrease, 7 percent). Oils are used mostly as insecticides in orchards; copper is used mostly in grapes, walnuts, rice, orange, and walnuts; and metam-sodium is used in carrots, processing tomatoes, and potatoes.

In contrast, some pesticide use increased. Pesticides with the greatest increase in pounds applied were the fumigants 1,3-D (860,000 pound increase, 10 percent), potassium n-methyldithiocarbamate (also called metam-potassium) (580,000 pound increase, 18 percent), and chloropicrin (460,000 pound increase, 9 percent). The increase in use of these fumigants was balanced by decreases in other fumigants. Therefore, total fumigant use decreased by 290,000 pounds (0.8 percent). Fumigants are mostly used in strawberries, carrots, processing tomatoes, and for structural pest control.

Different pesticides are used at different rates. In California, most pesticides are applied at rates of around 1 to 2 pounds per acre. However, fumigants are usually applied at rates of hundreds of pounds per acre. Thus, comparing use by pounds will emphasize fumigants. Comparing use among different pesticides using acres treated gives a different picture.

Total acres treated with all pesticides in 2007 was 68 million, a decrease from 2006 of 7 million (10 percent). By acres treated, the non-adjuvant pesticides with the greatest use in 2007 were

sulfur, glyphosate, oils, copper compounds, and oxyfluorfen. Most of the decrease in total acres treated was from decreases in copper, indoxacarb, paraquat dichloride, chlorpyrifos, and glyphosate. Most of the increase in acres treated was from flonicamid, pendimethalin, beta-cyfluthrin, imidacloprid, and propamocarb hydrochloride. Glyphosate, oxyfluorfen, and pendimethalin are herbicides used mostly in almond, cotton, and grapes; flonicamid is a new insecticide mostly used in cotton; beta-cyfluthrin is another new insecticide mostly used in alfalfa and orange, however, its increase was matched by equal decrease in use of the similar pesticide cyfluthrin; imidacloprid is an insecticide used mostly in grapes and lettuce; and propamocarb hydrochloride is a fungicide used mostly in lettuce.

DPR data analyses have shown that pesticide use varies from year to year depending upon pest problems, weather, acreage and types of crops planted, economics, and other factors. The winter and spring of 2007 was relatively dry which probably resulted in less weed and disease pressure. There were generally less insect problems in 2007 as well. These conditions explain most of the decreases in pesticide use of all kinds. The main exception to this pattern was a slight increase in miticides possibly due to more mites from especially high temperatures in July and August. Also, there were some increases in the use of several newer, reduced-risk pesticides.

In the following tables, use is given by pounds of AI applied and by acres treated. Acres treated means the cumulative number of acres treated; the acres treated in each application are summed even when the same field is sprayed more than once in a year. (For example, if the same acre is treated three times in a calendar year with an individual AI, it is counted as three acres treated).

Almonds

Almonds are California's largest tree nut crop in total dollar value and acreage. They are the largest horticultural export from the United States. A record crop of 1.38 billion pounds of almonds, 24 percent more than the previous year was harvested in 2007. Almond shipments to overseas markets increased to 866.4 million pounds, up 24 percent over the previous year, led by strong growth in Europe, Asia and the Middle East.

Table 11A. *Total reported pounds of all active ingredients (AIs), acres treated, acres planted, and prices for almond each year from 2003 to 2007. Planted acres from 2003 to 2006 are from CDFA 2007; planted acres in 2007 are from NASS, May 2008a; marketing year average prices from 2003 to 2007 from NASS, July 2008b.*

There are three distinct almond growing regions in California: the Sacramento Valley, Central San Joaquin Valley and Southern San Joaquin Valley. Weather conditions and pest pressure can vary greatly from the northern to the southern region. Overall, pesticides applied in 2007 were down compared with 2006. This was due in large part to a relatively dry spring and a corresponding reduction in fungicide sprays. 2007 also saw a reduction in some insecticide sprays and an increase in others particularly, to protect the crop from insect damage that could compromise compliance with European Union (EU) aflatoxin standards. Also noted in 2007 was a continuing shift to more reduced risk insecticides. This is part of a trend where growers are moving away from older, more broad-spectrum pesticides to newer, reduced-risk materials.

Key pests in almonds are navel orangeworm (NOW), San Jose scale (SJS), peach twig borer (PTB), web-spinning mites, and ants. The best program to control NOW is winter sanitation. Growers are becoming more conscious about removing mummy nuts down to less than two per tree. Other essential elements of a successful NOW strategy include a May spray and hull split sprays using materials such as methoxyfenozide, chlorpyrifos, and bifenthrin. Acres treated with oil increased 7 percent in 2007. Dormant sprays with oil alone were applied to control low to moderate populations of SJS. Other insecticides were added with the oil to control high populations of SJS, PTB, and oblique-banded leafroller, particularly in the southern regions.

Spring 2007 was quite dry in comparison to 2006. As a result, acres treated with most fungicides were down. Acres treated with azoxystrobin were down 64 percent. Part of the decease is due to resistance to the strobilurins that has developed with alternaria and almond scab. Use of pyrimethanil was one material that increased in 2007. One explanation for the increase in pyrimethanil could have been an attempt to address the resistance issue.

In-season use of chlorpyrifos in 2007 was down due in large part to the lack of leaffooted bugs, which were a problem statewide in 2006. In general, worms were not a big problem in 2007. Acres treated with bifenthrin were up in 2007 primarily for navel orangeworm control. A new

bifenthrin product that has been shown to be effective against NOW, but that does not flare mites like esfenvalerate and some of the older pyrethroids. Use of bifenthrin is expected to continue to increase in 2008, primarily because it is reportedly working well in trials and due to the concern for aflatoxin. One bifenthrin treatment for NOW and a reduced-risk methoxyfenozide spray to control PTB, when necessary, are replacing azinphos methyl and phosmet at hull split.

Acres treated with abamectin, which is used for mites, increased in 2007. Mites were a problem in some areas due to the drier weather. Abamectin is also used for ants. Growers reported treatment for ants in all growing regions using abamectin or pyriproxyfen. The use of abamectin for both mites and ants may have been a partial factor in the increased use. Also, some growers reportedly prefer to use abamectin as a prophylactic treatment for mites to avoid late season flair ups. In addition, the price of abamectin was down. Acres treated for mites with etoxazole and spirodiclofen also increased in 2007. Both materials are relatively new and seem to be gaining favor with growers. Use of etoxazole is expected to increase, in proportion to the decrease in propargite and bifenazate. Use of another new material, s-methoprene, is starting to show up and reportedly will increase in 2008.

Acres treated with herbicides and pounds applied in 2007 increased slightly but overall were pretty close to 2006. Use of herbicides increased because there was a greater proportion of young orchards, and thus greater exposure of the ground to sunlight, which results in more weed growth. The use of carfentrazone-ethyl went down and use of glufosinate-ammonium increased. Glufosinate-ammonium and paraquat are reportedly used as alternatives to control weeds resistant to glyphosate. Acres treated with pendimethalin nearly doubled in 2007.

Total pounds applied and acres treated with the fumigants 1,3-dichloropropene, methyl bromide and sodium tetrathiocarbonate increased in 2007. Use of these fumigants is closely tied to the recent spurt of newly planted acreage and replanted orchards. Newly planted acreage normally requires a one-time preplant fumigation. Almonds planted on old orchard or vineyard ground are usually fumigated at the maximum or close to the maximum rate.

Wine Grapes

In 2007, roughly 62 percent of California vineyards produced wine grapes. There are four major wine grape production regions: 1) North Coast (Lake, Mendocino, Napa, Sonoma, and Solano counties); 2) Central Coast (Alameda, Monterey, San Luis Obispo, Santa Barbara, San Benito, Santa Cruz, and Santa Clara counties); 3) Northern San Joaquin Valley (San Joaquin, Calaveras, Amador, Sacramento, Merced, Stanislaus, and Yolo counties); and 4) Southern San Joaquin Valley (Fresno, Kings, Tulare, Kern, and Madera counties). Factors that influence changes in pesticide use on wine grapes include weather, topography, pest pressures (which vary by region), competition from newer pesticide products, application restrictions, efforts by growers to reduce costs, and increasing emphasis on sustainable farming. The pooled figures in this report may not reflect differences in pesticide use patterns between production regions.

Total wine grape acres treated with pesticides remained nearly constant from 2006 to 2007, while total pounds of pesticide applied increased by 1 percent.

In 2007, sub-freezing temperatures in January were a major cause of concern, but the following mild temperatures aided vine recovery. Warm temperatures in April stimulated vigorous vine growth. High temperatures in early July and August caused some concern, with some fruit shriveling reported in Madera County. Overall, the warm temperatures in early August led to early harvest start dates. Grape harvesting started in early August, continuing through mid-November. Minor amounts of precipitation were reported in various regions in late September, but there were minimal crop damages.

The major insecticides applied in 2007 by acres treated were imidacloprid, methoxyfenozide, oils, chlorpyrifos, bifenazate, abamectin, dinotefuran, and buprofezin. The acres treated with insecticides increased by 17 percent from 2006. Factors that may have contributed to the increased insecticide use were spreading infestations of vine mealybug and increased use of reduced-risk products, which sometimes require more frequent and better-timed applications to be effective. Vine mealybug is known to infest 17 counties, with an additional 4 counties of questionable status (CDFA, 2008). Methoxyfenozide and *Bt* products control various moths. Dinotefuran is applied for control of sharpshooters and mealybugs. In 2007, acreage treated with oils increased greatly (Table 12C). Oils have many attractive, broad-spectrum properties and are low-risk. Increasingly mixed with fungicides, oils can replace a surfactant and eradicate mildew growth, as well as suppressing mites and insects such as grape leafhoppers. Bifenazate is a selective alternative to older, higher-risk miticides, which have longer worker re-entry periods.

Acres treated with sulfur increased by 4 percent but acres treated with all other fungicides decreased by 4 percent. Sulfur, copper products, myclobutanil, boscalid, pyraclostrobin, and trifloxystrobin were the most-used fungicides in terms of acres treated. Acres treated with lime sulfur in early 2007 against overwintering disease inoculum decreased by 31 percent. Copper,

used to treat downy mildew and botrytis bunch rot, was applied to 11 percent fewer acres compared to 2006. Acres treated with sulfur increased slightly from 2006 (Table 12C). Some materials applied for phomopsis or *Botrytis* infections early in the year also control mildew.

The acres treated with herbicides decreased by 11 percent in 2007 compared to 2006. This decrease was most likely due to the relatively dry conditions in mid-winter, which resulted in lower weed pressure in February and March. Herbicides used most in wine grapes by acres treated were glyphosate products, oxyfluorfen, paraquat, flumioxazin, and simazine. The acres treated with simazine and paraquat decreased dramatically, by 33 percent and 27 percent respectively. In contrast, flumioxazin-treated acreage increased by about 30 percent from 2006; this recently registered herbicide, presents less risk of ground water contamination than simazine or paraquat, due to relatively short environmental half-lives (CDPR, 2008).

Fumigants applied for wine grape production decreased by 14 percent in 2007 compared to 2006 in terms of acres treated. The decrease was due to less use of aluminum phosphide and 1,3-dichloropropene. Field applications of the general-purpose soil fumigant methyl bromide, that is being phased out, was decreased by 38 percent.

Plant growth regulators (PGR) are not widely used in wine grapes. Acres treated with PGR decreased by -4 percent in 2007 to about 9100 acres compared to 2006. The most common PGRs were gibberellins, which are applied in early spring in order to lengthen and loosen grape clusters. Less compact clusters may be less vulnerable to berry splitting and bunch rot.

Cotton

Cotton is grown for fiber, oil, and animal feed and is one of the five most widely grown crops in California. Two main kinds of cotton are grown: upland and Pima. For the past few years Pima cotton acreage has been increasing and upland cotton decreasing but from 2006 to 2007 acreage of both decreased although Pima had a smaller decline. In 2007, for the first time, there were more Pima acres than upland acres. Total cotton acreage decreased by 19 percent. Some upland cotton has also been genetically modified to be tolerant to the herbicide glyphosate (Roundup); acres planted with Roundup Ready cotton decreased by 13 percent from 2006 to 2007. Most cotton is grown in the southern San Joaquin Valley, but a small percentage is grown in Imperial and Riverside counties and several counties in the Sacramento Valley.

Acres planted with cotton decreased 19 percent from 2006 to 2007, continuing the yearly decreases seen since 2004. However, Pima acres decreased only by 5 percent. For the first time ever there were more Pima acres than upland acres. Total pesticide use on cotton decreased from 2006 to 2007, partly because acres planted decreased. However, even measured as use per acre planted, pesticide use still decreased. Acres treated decreased by 35 percent and pounds of AI decreased by 38 percent. Acres treated and pounds of AI of the main AI types decreased. The use of harvest aids, which are chemicals used to defoliate or desiccate cotton plants before harvest, decreased by 27 percent in acres treated and 29 percent by pounds of AI; insecticide use decreased by 46 percent in acres and 61 percent in pounds, and herbicide use decreased by 42 percent in acres and 40 percent in pounds. Although acres treated with fungicides remained nearly the same in 2007 as in 2006, the pounds of fungicides decreased by 34 percent. The decrease in most pesticides occurred because 2007 had few pest problems. The winter of 2006 – 2007 was dry and cool and this probably kept overwintering pest populations low.

The most used insecticide by acres treated in 2007 was abamectin followed by flonicamid, aldicarb, imidacloprid, and acetamiprid. Use of nearly all the top insecticides decreased, except for flonicamid, which was used for the first time in 2007, and imidacloprid, with treated acres increasing by 15 percent, although pounds decreased. All the organophosphate pesticides decreased. The miticides abamectin and dicofol had only relatively small decreases (each decreased 16 percent). Two newer miticides, etoxazole and spiromesifen, which increased in 2006, decreased in 2007 (by 45 percent and 61 percent, respectively).

The decrease in insecticide use was primarily due to few pest problems in most areas in 2007 and fewer acres planted. Lygus bug populations started the season at low levels, probably because the dry winter kept their overwintering host plants down. However, later in the season lygus increased, possibly because of increased acres of safflower and corn, which can be good

alternative lygus hosts. Aphid populations were higher in 2007 than 2006 but less than other years. Other arthropod populations were relatively low.

The herbicides with most acres treated in 2007 were glyphosate, pyrithiobac-sodium, trifluralin, oxyfluorfen, and pendimethalin. The herbicides with greatest decrease were paraquat dichloride (85 percent in acres treated), pyraflufen-ethyl (57 percent), and oxyfluorfen (48 percent). Some of these AIs are used both as harvest aids and herbicides; here it is assumed if use occurred between August and November it was used as a harvest aid, otherwise as an herbicide. Herbicide use decreased probably because the relatively dry winter kept weeds down.

The major harvest aids in 2007 were ethephon, thidiazuron, diuron, mepiquat chloride, and pyraflufen-ethyl. Although mepiquat chloride is included here among the harvest aids, it is actually a growth regulator and is typically used mid-season. Use of nearly all harvest aids and growth regulators decreased from 2006 to 2007, except for cyclanilide. The largest percent decreases were mepiquat chloride (48 percent), sodium chlorate (42 percent), and S,S,S-tributyl phosphorotrithioate (41 percent). These are mostly older harvest aids and are being replaced somewhat by newer chemicals, such as pyraflufen-ethyl, carfentrazone-ethyl, and especially some new cyclanilide products, which have more predictable results. Reduced use of harvest aid and plant growth regulators were also indirectly related to the relatively low insect and mite pest pressure in 2007. When insect pressure is lower and fruit are set more evenly on the plants, there generally is less need for growth regulators due to fruit competition with vegetative growth for nutrients and carbohydrates. Preparation for harvest is also typically easier in plants where vigor is more balanced due to good fruit distribution and more even and less vigorous growth.

Fungicides are not widely used in cotton, but their use has been increasing most years between 2002 and 2007 because of increased problems with seedling diseases. The most commonly used fungicide both by pounds and acres treated is azoxystrobin and its use increased by 3 percent, both by pounds and acres treated. By pounds, the only other fungicide to increase was metalaxyl (6 percent); pounds of all the other main fungicides decreased by 50 to 65 percent. By acres treated, azoxystrobin was practically the only fungicide applied. Nearly all other fungicides are used as seed treatments and are not applied to the field. Azoxystrobin is applied to cotton fields at planting to control seedling diseases. Azoxystrobin use increased in 2007 and in recent years because the cool spring weather was conducive to seedling diseases and because of other factors that made re-planting fields nearly cost-prohibitive. These factors include: (1) the increasing cost of planting seed, particularly the transgenic varieties; and (2) difficulties in maintaining soil moisture for replanting, or excessive costs of additional water needed if problems with soil moisture availability are apparent after replanting. *Rhizoctonia* was the most common seedling disease and was worse in 2007 than most other years.

Table and raisin grapes

Table and raisin grapes comprised approximately 38 percent of California's total grape crop in 2007, the rest being wine grapes. These categories shift depending on market conditions, since some grape varieties can be used for more than one purpose. Thompson Seedless is the leading raisin grape variety, while Flame Seedless is the leading table grape variety. California produced about 1,947,000 tons of raisin grapes and 754,000 tons of table grapes in 2007. Despite reported vine stunting caused by sub-freezing temperatures in January, statewide table grape and raisin tonnage increased by 37,000 tons and 114,000 tons, respectively, relative to 2006 production.

Two percent fewer acres were planted to table and raisin grapes in 2007. Total acres treated with the major categories of pesticides decreased by 4 percent, while total pounds of applied pesticides increased by 7 percent. The increase in pesticide use can be attributed to increased applications of insecticides, fumigants, and fungicide/insecticides.

In 2007, sub-freezing temperatures in January were a major cause of concern, but the following mild temperatures in subsequent months, aided vine recovery. Warm temperatures in April stimulated vigorous vine growth. Record high temperatures in early July caused some concern, but little fruit shriveling was reported. Table grape harvests began in the Central Valley in early July, continuing into early November for the late ripening varieties. Raisin grape harvesting began in late August, with the majority of the crop dried and removed from the field by late September. Minor amounts of precipitation were measured in the Central Valley in the last week of September, but the damage to the raisin crop was minimal. In general, table and raisin grapes were of good size and quality and the harvest was about 3 percent larger in 2007 than 2006.

Insecticides that experienced a significant increase in use in 2007 include imidacloprid, oils, spirodiclofen, and buprofezin. Factors that may have contributed to the increased insecticide use were spreading infestations of vine mealybug and increased use of reduced-risk products, which sometimes require more frequent and better-timed applications to be effective. Both imidacloprid and buprofezin are used to control vine mealybug. In 2007, acreage treated with oils increased greatly (Table 14C). Oils have many attractive, broad-spectrum properties and are low-risk. Increasingly mixed with fungicides, oils can replace a surfactant and eradicate mildew growth, as well as suppressing mites and insects such as grape leafhoppers. The active ingredient spirodiclofen was registered for use in California, in 2007. Spirodiclofen is a miticide in the

tetronic acid class of chemicals (USEPA, 2005). In its first year of registration, 3,815 pounds of the active ingredient was applied to 14,059 acres.

Disease pressure was fairly light in 2007 compared to 2006, resulting in a decrease in fungicide use. Acres treated with sulfur decreased by 2 percent, due to reduced powdery mildew pressure. Fungicides most used for table and raisin grape production in 2006 by acres treated were sulfur, copper, myclobutanil, boscalid, pyraclostrobin, trifloxystrobin and tebuconazole. Most of these as well as potassium bicarbonate, triflumizole, and fenarimol provide good to excellent control of powdery mildew, which is the main reason for fungicide use in San Joaquin and Coachella Valley vineyards. Table 14C shows decreases in acres treated with several of those fungicides and cyprodinil, which is effective against *Botrytis* bunch rot. Copper use decreased dramatically in 2007, down 40 percent from 2006; this was likely due to reduced disease pressure from downy mildew and summer bunch rot. Use of sulfur dioxide, the major postharvest fungicide applied to table grapes, was up by 26 percent by weight.

Decreased herbicide use reflected a relatively dry winter season, resulting in reduced weed pressure in early spring. The most-used herbicides by acres treated were glyphosate, paraquat dichloride, simazine, oxyfluorfen, oryzalin, and glufosinate-ammonium. Table 14C lists several of these chemicals as herbicides with significant decreases in acres treated in 2007. Flumioxazin and glufosinate-ammonium applications increased in 2007 by 42 and 36 percent, respectively. Flumioxazin is a pre-emergent herbicide with a lower potential to contaminate ground water than simazine, while glufosinate-ammonium is a post-emergent with properties similar to glyphosate.

Total vineyard acres treated with fumigants increased by 140 percent in 2007 compared to 2006. The two most-used soil fumigants by pounds of active ingredients, are the preplant nematicide 1,3-dichloropropene and sodium tetrathiocarbonate for nematodes and phylloxera . Methyl bromide applied for postharvest treatment of grapes for export was nearly unchanged from 2006, amounting to about 9000 pounds. By pounds of active ingredient, use of aluminum phosphide, the main postharvest fumigant for raisins, increased by 53 percent. This represents an increase of roughly 1,200 pounds from 2006, placing the year's use close to that of 2005 and below the five-year average.

Raisin and table grape acres treated with plant growth regulators (PGR) were roughly the same as in 2006, with a marginal decrease of 0.3 percent. Total pounds of PGR applied increased by 19 percent, which is directly attributable to an increase in hydrogen cyanimide applications in Coachella Valley (>77 percent of all hydrogen cyanimide uses both in pounds and acres treated was done in Coachella Valley). Hydrogen cyanimide is sprayed during the dormant period to promote increased and uniform budbreak in areas that have warmer winters. Total acres treated with hydrogen cyanimide increased by 10 percent. By acres treated, gibberellin was the most-used PGR. It is a low-dose compound, sprayed between mid-May and early June to reduce fruit set and increase fruit size. By acres treated, forchlorfenuron, which is more expensive but used in the same way as gibberellin, was used in only 2% of the acres. Forchlorfenuron is mainly used on grape varieties that are not tolerant of gibberellins.

Alfalfa

Alfalfa hay is produced for animal feed in California. Most counties produce some alfalfa hay, but more than half of the state's production comes from Fresno, Kern, Imperial, Merced, and Tulare counties. Harvested alfalfa acres decreased by 6 percent in 2007 compared to 2006, but the price per ton increased by 41 percent from 2006 to 2007. The dairy industry remains the biggest market for alfalfa hay. The increased price for hay was due to higher milk prices, premium paid for corn in ethanol production and low hay supplies from other western states that usually ship large quantities of alfalfa into California to augment local production. The total pounds of pesticide active ingredient applied decreased by 4 percent in 2007 compared to 2006. Similarly, the acres treated with pesticides decreased by 20 percent in 2007 relative to 2006.

Table 15A. *Total reported pounds of all active ingredients (AIs), acres treated, acres harvested, and prices for alfalfa each year from 2003 to 2007. Statewide, insecticide use on alfalfa decreased by 11 percent in pounds of AI and by 20 percent in acres treated in 2007 compared to 2006, which were greater declines than the 6 percent decrease of alfalfa acres harvested. The decrease in acres treated with insecticides was mainly from declines in chlorpyrifos (13 percent), methomyl (49 percent), cyfluthrin (60 percent), (s)-cypermethrin (41 percent), and indoxacarb (49 percent). In contrast, acres treated with beta-cyfluthrin increased by about 30 times in 2007 compared to 2006; this increase was probably due to a switch from cyfluthrin to beta-cyfluthrin. Due to growers' awareness, uses of products (e.g. chlorpyrifos) with surface water quality concerns are expected to decline over time.

The decrease in chlorpyrifos and methomyl was mainly in the San Joaquin Valley. Decreased use of in indoxacarb was mainly in the San Joaquin Valley, and Imperial Valley. Insecticide use is a reflection of the intensity of pest pressure during the season. The statewide decrease for insecticide use in pounds and acres treated may be due to less insect pressure of western yellow striped armyworm, beet armyworm, alfalfa caterpillar, and Egyptian alfalfa weevil in 2007 relative to the preceding years.

Statewide, herbicide use in pounds and acres treated decreased by 7 percent and 16 percent respectively, in 2007 compared to uses in 2006. This decrease may be due to less weed pressure because of the relatively dry spring in 2007 compared to 2006 and because there were fewer acres planted. Use of most of the top 20 high use herbicides decreased, except for glyphosate, pendimethalin, EPTC, and benefin.

The decrease in herbicide use occurred mainly in the Sacramento and San Joaquin Valleys. The increase in glyphosate use may be attributed to the brief introduction of genetically modified Roundup Ready (glyphosate) alfalfa varieties. A court mandate in 2007 halted planting of new

acreage of Roundup Ready alfalfa but allowed existing acres to continue producing. Since growers could not plant new Roundup Ready alfalfa, they returned to the use of pre-plant herbicides benefin and EPTC.

Processing Tomato

Processing tomato growers planted 301,000 acres in 2007, a six percent increase over 2006. The highest concentration of processing tomatoes continues to be located in the southern San Joaquin Valley, with Fresno County leading state production with 40 percent of the crop—or 119,000 acres—followed by Yolo County (37,600 acres), San Joaquin County (30,100 acres), and Kings County (24,800 acres).

Total processing tomato production increased by 20 percent from 2006 while total pounds of AI decreased by 13 percent, from 12 million pounds in 2006 to 11 million pounds in 2007. Acres treated decreased by 9 percent, from 3.0 million acres in 2006 to 2.7 acres in 2007. This decrease was attributable to a very dry spring and lack of seedling and spring foliar diseases, such as bacterial speck. This is the lowest pesticide use (by pounds) since 2002. Sulfur and metam-sodium (and potassium forms) accounted for a large percentage of pesticide AI applied—nearly 85 percent of the total pounds applied to tomatoes in 2007.

The number of acres treated with insecticides increased from 2006 to 2007, partly due to pressure from aphids, lepidopterous pests (tomato pinworm, armyworms), and concerns about tomato spotted wilt virus—vectored by western flower thrips. Dimethoate remains the highest use insecticide in pounds AI in 2007, increasing nearly 31 percent from 42,235 pounds in 2006 to 55,161 pounds in 2007. In terms of acres treated, dimethoate increased from 92,309 acres (2006) to 121,219 acres in 2007. Dimethoate is inexpensive, and works well for aphid control. Bifenthrin had the largest percentage increase in use, going from only 4 pounds in 2006 to 4,140 pounds in 2007 and from 38 to 7,144 acres treated. Registered on tomatoes in 2007, bifenthrin is being used to control mites, stinkbugs, and in an attempt to manage virus diseases—spotted wilt particularly. Emamectin benzoate use remained the same compared to 2006, 59,650 acres treated or 6th largest among insecticides, but pounds of use was low, only, 609 total pounds in 2007. Lepidopteran pests and stinkbugs were, again, a major concern that led to similar overall use of worm materials as 2006, though methoxyfenozide seemed to be the preferred insecticide (an increase from 2006 of over 2,000 pounds) while indoxacarb, lambda-cyhalothrin, and tebufenozide all decreased in pounds applied and acres treated. The only other insecticide of note was carbaryl. Carbaryl use increased significantly in 2007 due to an outbreak of ground beetles during transplanting and seedling emergence, increasing 150 percent from 2006 to 25,255 pounds AI applied—trailing only dimethoate in total insecticide pounds used in 2007.

Despite the increase in acres planted, acres treated with herbicides dropped by 119,000 acres in 2007 compared to the year before. Likewise, total pounds of herbicides also decreased in 2007; mostly due to a dry winter and spring that allowed cultivation. Transplant tomato acres continue to increase over direct-seeded acres, contributing to decreases in pounds of s-metalochlor (down 5 percent), metam sodium, and potassium N-methyldithiocarbamate (combined pounds, down 12 percent). Many of the fallow bed herbicides were down in pounds and acres treated due to dry weather conditions (pounds of glyphosate, down 13 percent; pounds of oxyfluorfen, down 68 percent; and pounds of paraquat, down 65 percent).

Sulfur, used for russet mite and powdery mildew during May, June, July and August decreased over 883,000 pounds compared to 2006 (down 11 percent). Acres treated with sulfur decreased similarly, (12 percent) from 304,000 acres in 2006 to 267,000 acres in 2007. Acres treated with chlorothalonil increased, up 27,000 acres or 23 percent, as did pounds of AI applied, also increasing from 2006—from 195,000 to 255,000 pounds, over a 30 percent increase in one year. Chlorothalonil, used to control black mold primarily, but also to limit defoliation and resulting sunburn, was the most used non-sulfur fungicide in 2007, surpassing mancozeb, in second place by pounds, with 25,000 pounds applied. Copper and mancozeb, together, decreased from 128,000 pounds in 2006 to 42,000pounds in 2007, mainly because spring weather did not favor the development of bacterial spot and bacterial speck.

Oranges

Oranges are the eighth highest value crop grown in California (California Agricultural Resource Directory 2007). Eighty-six percent of California oranges are grown in the San Joaquin Valley (Fresno, Kern and Tulare counties) with over half of the total in Tulare county alone. The rest are grown in the interior region (five percent, in Riverside and San Bernardino counties) and on the south coast (about seven percent of the state's acreage, mostly in Ventura and San Diego).

***Table 17A**. Total reported pounds of all active ingredients (AIs), acres treated, bearing acres, and prices for oranges each year from 2003 to 2007. Bearing acres from 2002-03 to 2005-06 are from CDFA 2007; bearing acres in 2006-07 are from NASS, September 2007; marketing year average prices (equivalent P.H.D.) in prices in 2001-02 to 2003-04 are from NASS, July 2005; prices from 2004-05 to 2006-07 are from NASS, July 2008b. A box is about 75 pounds of oranges. "P.H.D." is an abbreviation for per hatch per day.*

Total pounds of pesticides used decreased significantly (16 percent) from 2006 to 2007. The total acres treated decreased by 5 percent while the price per box increased 15 percent. The most significant decrease was in the amount of fungicides used. The number of bearing acres continued to decrease, a trend since 2001. The year began with a hard freeze, causing substantial

damage to the crop before growers were able to harvest. Preliminary freeze damage to citrus in Fresno County alone was assessed at over $100 million dollars. The effects of the freeze were seen throughout the year with fruit going to juice rather than fresh market, tree removal, extra pruning to remove frost-damaged limbs and in some areas, loss of flowering and fruit set. The summer saw record-breaking high temperatures and extremely low humidity in the citrus-growing regions. As a result, mite populations increased and growers sprayed more miticides.

Overall, acres treated with insecticides increased by 7 percent, up to 2005 levels. Oil, spinosad, pyriproxyfen, chlorpyrifos, *Bacillus thuringiensis (Bt)*, and beta-cyfluthrin were the most widely used insecticides by acres treated. Oil is a broad-spectrum insecticide for mites and scales and is also used as an adjuvant in pesticide treatments. The majority of the increased use came from increases in the use of beta-cyfluthrin, acetamiprid, *Bt*, pyriproxyfen, and spinosad. There were also increases in use of dimethoate and spirodiclofen. The increase in beta-cyfluthrin was almost exactly balanced by a decrease in cyfluthrin. Acetamiprid was not used in great amounts or on large acreages in 2006 but use patterns increased significantly in 2007. This is probably due to growers replacing chlorpyrifos with this insecticide and also because it was used in an areawide treatment program for the glassywinged sharpshooter. *Bt* is used for caterpillar pests and its increased use is tied to higher pest pressure from lepidopterans. In 2007, growers saw a significant increase in citrus cutworm and responded by using *Bt*. Pounds of pyriproxyfen increased by 29 percent. It is used for scale control. Resistance could be increasing, leading to the need for greater amounts of the insecticide. Spinosad is used for citrus thrips. Pounds used and acres treated with this insecticide both increased significantly (17 percent and 16 percent, respectively). 2007 appears to have been a heavy year for thrips. Spiridoclofren and pyridaben are both miticides. The increase in spiradoclofren use, a newly registered product, coupled with the decrease in pyridaben use, is due to growers switching in order to try out the newer AI.

In contrast, use of some insecticides decreased. Use of chlorpyrifos, a broad-spectrum insecticide, declined significantly. It is used primarily for citricola scale control but resistance has been documented. Growers are shifting to other insecticides such as imidacloprid and acetamiprid.

Acres treated with fungicides decreased by 32 percent between 2006 and 2007. That decrease was due to the decrease in use of copper. Copper is the most widely used fungicide on oranges. It is used to prevent *Phytophthora gummosis*, *Phytophthora* root rot, and fruit diseases such as brown rot and Septoria spot. These diseases are exacerbated by wet weather. 2007 was a dry year and fungal diseases were not as severe as in an average rainfall year.

Acres treated with herbicides slightly increased (by 4 percent) between 2006 and 2007 but use did not go back up to 2005 levels. Glyphosate was used the most both in pounds and acres treated, followed by diuron and simazine. The herbicide glyphosate is used to control weeds post-emergence and 4 percent more was used in 2007. Diuron and simazine are used for pre-emergent weed control. Pounds of simazine and diuron used decreased by 11 percent and 6 percent respectively in 2007. The use of pendimethalin almost doubled. Decreased use of simazine and diuron is partially due to ground water regulations.

Rice

California's Sacramento Valley contains more than 95 percent of the state's rice acreage. The remainder is in north to central San Joaquin Valley. The leading rice-producing counties are Colusa, Sutter, Butte, Glenn, and Yolo. Approximately 500,000 acres in the Sacramento Valley are of a soil type restricting the crops to rice or pasture. The remainder of the acreage has greater crop flexibility.

Table 18A. *Total reported pounds of all active ingredients (AIs), acres treated, acres planted, and prices for rice each year from 2003 to 2007. Planted acres from 2003 to 2006 are from CDFA 2007; planted acres in 2007 are from NASS, June 2008; marketing year average prices from 2003 to 2005 are from NASS, July 2004 and July 2006; 2006 and 2007 prices are from NASS, July 2008b. Pesticide use increased approximately 9 percent from 2006 to 2007 in terms of acres treated, but decreased approximately 11 percent in terms of pounds AI applied. Pounds of AI decreased while acres increased primarily because copper use decreased and copper is applied at high pounds per acre treated and because use of most other AIs increased. Rice acres planted increased by 2 percent. In 2007, there were no major shifts in pest pressure. Herbicides accounted for most of the pesticide use; approximately 77 percent of non-adjuvant pesticide acres treated has been with herbicides. Herbicide use increased by approximately 12 percent from 2006 to 2007. Insecticide use has been decreasing generally and fungicide use increasing since 1993; from 2006 to 2007, acres treated with insecticides increased 38 percent and fungicides increased 27 percent. Major pesticides with the largest percent increases in acres treated include 2,4-D, lambda-cyhalothrin, clomazone, azoxystrobin, and s-cypermethrin. Pesticides with the largest percentage decreases in acres treated include carfentrazone-ethyl, molinate, glyphosate, copper, and thiobencarb.

Lambda-cyhalothrin is the most widely used insecticide by acres treated and its use increased 50 percent in 2007 due to price. Lambda-cyhalothrin is off patent, and with the passage of AB1011, the price dropped to $3.00 per acre. The price of s-cypermethrin was initially lowered to compete with lambda-cyhalothrin. Both insecticides are used primarily for rice water weevil control and secondarily for armyworm and tadpole shrimp control. Insect pressure is low for California rice and these insecticides are used on approximately 10 percent of all rice planted in California. Copper sulfate is also used to control tadpole shrimp,, however, copper sulfate prices were up this year. Also, the product binds to straw residue making it less effective, so growers turn to pyrethroids to control tadpole shrimp soon after flooding.

Copper sulfate is the only algaecide registered for use on California rice, and one of the few products acceptable for organic rice production. The product doubles as a control for tadpole shrimp, which is very important to organic rice growers. Copper sulfate is only used early season when algae mats cover the field before the rice breaks the water surface. Factors that contributed

to the 37 percent decrease in use of copper sulfate include: 1) algae pressure was less due to the unusual weather patterns in 2007 (wet in early winter, with excessively hot July) resulting in less algal pressure at planting; and 2) an increase in the price of copper sulfate.

Azoxystrobin is a reduced-risk foliar fungicide. Disease pressure is low for California rice, which is the reason azoxystrobin is used on only approximately one-fifth the total acres planted. In addition, some growers used the product as a preventative for disease control and to increase yield.

The major herbicides by acres treated in rice in 2007 were propanil, triclopyr, clomazone, cyhalofop-butyl, penoxsulam, thiobencarb and bispyribac-sodium. Use of nearly all the major herbicides increased slightly, except for molinate, carfentrazone, and thiobencarb. Reasons for this include the decreased use of molinate for watergrass control (it is being phased-out) and the decreased use of thiobencarb for sprangletop control (due to its narrow timing window for effectiveness, and watergrass resistance). Control of ricefield bulrush with carfentrazone has had difficulties and penoxsulam has emerged as a good control for this weed. Resistance to molinate, carfentrazone and thiobencarb also accounts for the increases in use of clomazone and propanil. Loss of into-the-water molinate and the reduced use of thiobencarb prompts the use of foliar herbicides (cyhalofop, propanil, bispyribac-sodium, and the liquid formulation of penoxsulam); these herbicides require draining the field or lowering the water level, which in turn increases sprangletop incidence and growers' increased use of cyhalofop-butyl. Glyphosate is used as a preplant herbicide in rice. The 45 percent decrease in glyphosate use probably reflects a more normal planting season allowing for adequate timing of spring tillage operations. However, glyphosate use can be expected to increase in the future as stale-seedbed systems become adopted for herbicide resistance management. A stale-seedbed consists of early spring seedbed preparation with no soil disturbance

Head Lettuce

Head lettuce is grown in four regions in the state: the central coastal area (Monterey, San Benito, Santa Cruz, and Santa Clara counties); the southern coastal area (Santa Barbara and San Luis Obispo counties); the San Joaquin Valley (Fresno, Kings, and Kern counties); and the southern deserts (Imperial and Riverside counties). In 2004, 59 percent of all California head lettuce was planted in the central coastal area, 17 percent in the southern coastal area, 12 percent in the San Joaquin Valley, and 11 percent in the southern deserts. California produces 70 to 75 percent of the head lettuce grown in the United States annually. In this analysis, the central and southern coastal areas are combined unless noted.

Pesticide use on head lettuce fluctuated from 2003 through 2007 (Table 19A). Use of all classes of pesticide declined from 2006 to 2007 (Figure 17). There was a 4 percent increase from 2006 to 2007 in acres of head lettuce harvested. Yield per acre dropped about one percent, but overall production increased by over 2 percent.

The major pesticides with the largest increase in acres treated were propamocarb hydrochloride, a newly registered fungicide, and the insecticides imidacloprid and acetamiprid (Table 19C). Major pesticides with the largest decrease were dimethoate, spinosad, permethrin, (s)-cypermethrin, esfenvalerate, dimethomorph, maneb, famoxadone, cymoxanil, pyraclostrobin, fosetyl-al, and mefenoxam. During 2007, the top insecticides used (by acres treated) were diazinon, spinosad, (S)-cypermethrin, permethrin, and imidacloprid. The main fungicides used were maneb, propamocarb hydrochloride, dimethomorph, boscalid, and fosetyl-al. Three herbicides dominated—propyzamide (pronamide), bensulide, and benefin. Metam-potassium (potassium n-methyldithiocarbamate) was the main fumigant used, followed by metam sodium. Fewer than 0.2 percent of planted acres were treated with chloropicrin, 1,3–dichloropropene, or methyl bromide.

From 2006 to 2007, insecticide use—as measured by acres treated—declined by 3 percent overall. Insecticide-treated acres rose by 6 percent in the coastal areas, but decreased by 14 percent in the southern deserts, and 16 percent in the San Joaquin Valley. The neonicotinoid insecticides imidacloprid and acetamiprid are used mostly to suppress lettuce and foxglove aphids. Use of imidacloprid in the coastal area increased by 45 percent, peaking in July; however, use actually decreased in other lettuce-growing regions. Use of acetamiprid increased in all regions, but primarily in the San Joaquin Valley where it was used on almost three times more acres in 2007 than in 2006. Throughout California from 2006 to 2007, use of dimethoate and acephate, traditionally used for aphid control, declined in all regions.

The insecticides spinosad and (S)-cypermethrin are used to manage larvae of beet armyworm and cabbage looper, primarily pests in the southern deserts. Use of these insecticides, as measured by acres treated, decreased in the southern deserts in 2007. Methomyl, used for worms, increased by 30 percent in the coastal area, but decreased by 32 percent in the southern deserts. Emamectin benzoate, used for worm pests, is a synthetically modified form of abamectin. Its use increased by 23 percent in the coastal area, but decreased in other regions. Use of permethrin, which is primarily used for controlling seedling pests in the southern deserts such as crickets, earwigs, cutworms, and sowbugs, decreased in that area by 44 percent. Diazinon use also decreased in the southern deserts, where it is often used for stand-establishment pests such as crickets, darkling ground beetles, earwigs, and sowbugs.

Diazinon is a preplant treatment applied for soil pests, and until 2005 was recommended for symphylans, which show up in some coastal fields. A recent trial showed better control by the pyrethroids lambda-cyhalothrin and (S)-cypermethrin. Use of diazinon increased by 9 percent in the coastal area, and use of lambda-cyhalothrin and S-cypermethrin decreased by 4 percent and 10 percent, respectively. Insecticides such as abamectin have replaced permethrin to manage leafminers. Abamectin use in 2007 increased by 9 percent in the coastal area due to mounting leafminer pressure.

Fungicide use by acres decreased by 7 percent from 2006 to 2007. Several active ingredients—both old chemistry and reduced risk, are rotated for downy mildew, a disease that has many pathovars. Maneb, used primarily to control downy mildew and prevent anthracnose, was again the dominant fungicide, as it has been every year since the early 1990s. In general, use of maneb declined from 2006 to 2007, as did that of dimethomorph, fosetyl-al, and famoxidone/cymoxanil. Use of fosetyl-al decreased in all lettuce-growing regions. A new reduced-risk product for downy mildew registered in 2005 contains equal amounts of the active ingredients cymoxanil and famoxadone. After 2005, use of this product declined in all lettuce-growing regions. (See Sulfur below for powdery mildew.)

In 2007, a new active ingredient for lettuce, propamocarb, was introduced for downy mildew. Although used on a few acres in the southern deserts in 2006, its use in 2007 in the central coast and San Joaquin Valley was second only to maneb's.

Lettuce drop (Sclerotinia drop) is another fungal disease with a shift in popular active ingredients. Use of iprodione fell in the coastal area and southern deserts from 2006 to 2007, but rose by 2 percent in the San Joaquin Valley. Use of boscalid, a reduced-risk material, continued to rise in all lettuce-growing regions except the southern deserts. Dicloran use also rose, except in the San Joaquin Valley. (See also chloropicrin below.) Sulfur is applied as a foliar treatment for powdery mildew, and along with the reduced-risk fungicide, azoxystrobin, is the only labeled product used to manage this disease. Use of sulfur and azoxystrobin decreased from 2006 to 2007 in all regions.

Herbicide use by acres treated decreased by 8 percent from 2006 to 2007. Use of propyzamide (pronamide), applied as a postplant–preemergence herbicide, decreased statewide by 8 percent from 2006 to 2007. As consistent with its use for the past ten years, propyzamide was applied to many more acres than the preemergent, bensulide, which targets small-seeded annual grasses and is not as effective as propyzamide in the coastal areas. Use of benefin, a pre-plant herbicide popular in the San Joaquin Valley, decreased statewide from 2006 to 2007.

Nematodes are not economic pests of head lettuce, so soil is primarily fumigated to control soil-borne diseases and suppress weeds. In 2007, fumigants, mostly metam-potassium, were used on about 3 percent of all planted lettuce acreage. Metam-potassium, like its cousin metam-sodium, is a broad-spectrum contact soil sterilant used on a handful of crops. Along with metam-sodium, it was used almost exclusively in the San Joaquin Valley. Used primarily in the desert, use of 1,3–dichloropropene fell 76 percent. Use of methyl bromide, used entirely in the coastal area, decreased by 75 percent. Chloropicrin is used to reduce soil populations of Verticillium wilt and lettuce drop alone or when combined with methyl bromide or 1,3–dichloropropene. In 2007, chloropicrin was used only in the coastal area, and use decreased by 77 percent.

Peaches and Nectarines

California ranks first in the United States in peach and nectarine production. In 2007 the state grew 84 percent of all peaches (including 70 percent of fresh market peaches and all of the processed peaches) and 92 percent of nectarines. Most freestone peaches and nectarines are produced in the central San Joaquin Valley, and are sold on the fresh market. Clingstone peaches, largely grown in the Sacramento Valley, are used exclusively for processing into canned and frozen products including baby food and juice. Nectarine and freestone peach acreages remained unchanged in 2007, while clingstone peach acreage decreased slightly. Peaches and nectarines are discussed together because pest management issues for the two crops are very similar.

Table 20A. *Reported total pounds applied, total acres treated, bearing acres, and crop prices for peaches and nectarines each year from 2003 to 2007. Bearing acres for peaches and nectarines from 2003 to 2006 are from CDFA 2007; bearing acres in 2007 are from NASS, July 2008a; marketing year average prices for fresh (freestone) peach from 2003 to 2005 are from NASS July 2004 and July 2006; 2006 and 2007 prices are from NASS July 2008b.*

Peach and nectarine acreage treated with the major categories of pesticides has fluctuated from year to year since 1995 without substantial increasing or decreasing trends (Figure 18). In 2007, total acres treated with pesticides and total pounds of pesticide AI applied decreased from 2006 levels by 17 percent and 23 percent respectively, even though there were only 1 percent fewer bearing acres in 2007. This decrease in pesticide use was chiefly due to few problems with insect and mite pests, and a warm, dry spring in the San Joaquin Valley (the major production area) that suppressed pest fungi and weed growth. Plenty of wintertime chill hours left trees "well rested" before spring bloom. Mild spring weather promoted strong, uniform bloom and heavy fruit set. Conditions for freestone peach and nectarine development were ideal: temperatures were high enough to prevent flesh corking and ensure good sugar content and excellent taste, but not hot enough to decrease fruit size. A cooler spring in the Sacramento Valley reduced the size of clingstone peaches, but not fruit quality. 2007 saw a bumper crop of high quality peaches and nectarines, with per acre yields 33 and 23 percent above 2006 levels, respectively. The price per ton of peaches was 17 percent lower than in 2006, however, and the nectarine price 35 percent lower, for an aggregate price decrease of 23 percent (Table 20B).

Total peach and nectarine acres treated with insecticides decreased by about 9 percent in 2007, due to relatively light pest pressure. The major insecticides used in peaches and nectarines were: oils; esfenvalerate; phosmet; the Oriental fruit moth (OFM) mating disruption pheromones E–8–dodecenyl acetate, Z–8–dodecenyl acetate, and Z–8–dodecenol; and spinosad. Spirodiclofen, a contact miticide newly registered for stone fruit, made a strong market debut (Table 20C). Oils are applied during the dormant season to forestall outbreaks of scales, mites, and moth pests. Esfenvalerate is a broad-spectrum chemical that may be used in dormant applications or during the growing season, including as an alternative to OFM pheromones. Spinosad and phosmet control moths and katydids, and spinosad is also effective against thrips. Acres treated with the major insecticides decreased except for OFM pheromones and spinosad. Acres treated with diflubenzuron, a broad spectrum insect growth regulator that controls moths, beetles, and katydids, increased sharply (Table 20C). These data suggest a trend toward reduced-risk insecticides. They are not more expensive than organophosphate insecticides, and have shorter re-entry periods. Other possible reasons for the trend include the declining effectiveness of phosmet for moth control and a reduction in the cost of mating disruption for OFM management because longer-lasting pheromone dispensers have become available. Acres treated with chlorpyrifos and pounds applied decreased by about 31 percent and 40 percent, respectively. Growers are being encouraged to use alternative chemicals to protect water and air quality.

In 2007, peach and nectarine acres treated with fungicides decreased by about 28 percent because most of the growing area experienced a warm, dry spring that inhibited disease development. The most-used fungicides by acres treated were sulfur, propiconazole, ziram, copper, iprodione, cyprodinil, pyraclostrobin/boscalid, and tebuconazole. Sulfur is the standard treatment for powdery mildew. Propiconazole is a low-dose chemical applied against fungi and powdery mildew. Ziram and copper are effective for leaf curl and shot hole disease, and ziram also controls scab. Cyprodinil is used against brown rot of blossoms and fruit. Pyraclostrobin and boscalid are reduced risk alternatives for mildew and fungus control. Tebuconazole is effective against brown rots, and to a lesser extent against powdery mildew, rust, and scab. Treatments with almost all of these chemicals decreased substantially (Table 20C).

There was a 15 percent decrease in total peach and nectarine acres treated with herbicide in 2007. The dry spring in the San Joaquin Valley limited weed growth, and low fruit prices may have motivated growers to cut costs where possible. Most-used herbicides by acres treated were

glyphosate, oxyfluorfen, 2,4-D, paraquat, and pendimethalin. Among those herbicides, only pendimethalin registered an increase in use, which was large (Table 20C). Grass weeds can be more important during a dry spring, and pendimethalin is an effective grass herbicide with good residual control.

Total acres treated with preplant fumigants declined by 18 percent. Total pounds of preplant fumigants applied fell even more, by about 32 percent. Growers may be applying lower rates and/or moving from broadcast application to spot or row treatments. Those changes save money, and also respond to regulatory encouragement to reduce emissions of volatile organic compounds (VOCs), which are precursors to ground level ozone formation. 1,3-D accounted for 76 percent of peach and nectarine acres treated. Methyl bromide and chloropicrin were applied to 15 and 9 percent of acres treated, respectively. Methyl bromide use decreased partly because it has become relatively expensive. Changing relationships between nematode infestations, rootstock choices, and application patterns also affect fumigant selection and use from year to year.

Pounds of methyl bromide used for postharvest treatment of peaches and nectarines fell by 42 percent in spite of the bumper crop in storage. New export protocols adopted by several countries allow alternative methods of postharvest pest control. Notably, in 2007 Mexico allowed more fruit to be imported without fumigation provided it was produced under a systems protocol program involving a farm plan with mandated pesticide treatments.

Strawberries

California produces 86 percent of the total U.S. production of 2,499 million pounds of strawberries. California produced 2,154 million pounds valued at more than $1,338 million. Strawberries are grown mostly for fresh market. Depending on market prices, some are processed. California strawberry production occurs primarily along the central and southern coast, with small but significant production occurring in the Central Valley.

Table 21A. *Total reported pounds of all active ingredients (AIs), acres treated, acres harvested, and prices for strawberries each year from 2003 to 2007. The amount of strawberry acres treated with pesticides increased 5 percent while acres harvested declined. This can in part be explained by a 4 percent increase in acres planted during this same period, thus accounting for pesticides used on those acres including some not harvested until the following year. Pounds of pesticide applied increased 3 percent from 2006 to 2007. Pounds of pesticide per acre treated decreased 2 percent from 2006 to 2007. Fungicides, followed by insecticides, account for the largest proportion of pesticides applied by acres treated. By acres treated, use of fungicides remained about the same, while insecticides increased by 28 percent, and herbicides increased by 45 percent. The major pesticides with greatest increase in acres treated from 2006 to 2007 were *Bacillus thuringiensis (Bt)*, quinoxyfen, sulfur, *potassium carbonate*, pyrethrins, malathion, bifenthrin, oil, and spiromesifen. The major pesticides with decreased use by acres treated were captan, pyrimethanil, and fenhexamid.

Fungicides continue to be the most used pesticides, as measured by acres treated. The most important fungal diseases of strawberries are Botrytis and powdery mildew. The major fungicides by acres treated in 2007 were sulfur, captan, pyraclostrobin, boscalid, myclobutanil, fenhexamid, fludioxonil, and cyprodinil. In general, fungicides effective against Botrytis fruit rot decreased, and those effective against powdery mildew increased in 2007. Dryer conditions in January and February decreased Botrytis risk. The older registered fungicides (captan, thiram, thiophanate-methyl, and benomyl) and the newly registered pyrimethanil, fenhexamid, and boscalid are generally used to control Botrytis fruit rot. Acres treated with all of these products decreased in 2007.

Less free moisture on leaves but high humidity favored powdery mildew in 2007. Conventional strawberry growers primarily used sulfur, myclobutanil, boscalid, pyraclostrobin, azoxystrobin, and quinoxyfen to control powdery mildew. Sulfur is inexpensive and is also used by organic growers. Sulfur, myclobutanil, azoxystrobin, and quinoxyfen use increased. Pyraclostrobin is frequently used in combination with boscalid. Both acres treated with these two products and pounds of active ingredient decreased in 2007. Use of mefenoxam, effective against *Phytophthora fragariae* (red stele) and *P. cactorum* (leather rot and crown rot), decreased 3 percent in 2007.

The major insect pests in strawberries are lygus bugs in the central coast. Worms (various moth and beetle larvae) especially cutworms and beet armyworms continue to be particularly troublesome in the southern coast. The major insecticides used in 2007 by acres treated were *Bt*, spinosad, malathion, bifenazate, bifenthrin, naled, fenpropathrin, methomyl, abamectin, spiromesifen, hexythiazox, pyrethrins, and methoxyfenozide. Acres treated with all of these major insecticides increased except methoxyfenozide (down 14 percent) and hexathiazox on mites (down 8 percent). *Bt* and spinosad, both biological pesticides, continued in 2007 to be the primary pesticides used to control worms. Spinosad is also effective against thrips. *Bt* use (all forms) increased by 71 percent percent while spinosad use increased by 6 percent. Increases of both were greater in the South Coast region than in the Middle Coast region. Spinosad has a longer residual action and is generally more effective so does not need to be applied as frequently as *Bt*. Methoxyfenozide and spiromesifen (up 56 percent), both newly registered, continue to be widely used to control cutworm and beet armyworm. Increased use of malathion (up 22 percent) and bifenthrin (up 31 percent) may have increased in part because of increased problems with lygus bug resistance. Fenpropathrin (up 5 percent), malathion, spiromesifen, bifenthrin and pyriproxyfen (up 37 percent) are effective against whiteflies. Pyriproxyfen is an insect growth regulator registered in 2002. *Bt* and spinosad, as well as pyrethrins (up 262 percent), are available for use by organic growers. Like *Bt*, pyrethrins have short residual activity

and so may require multiple sprays. Perhaps due to recent reductions in cost, imidacloprid use increased by 166 percent as generic products have become available.

Increased two-spotted spider mite and red spider mite pressure resulted in 20 percent increased use of bifenazate, which is effective and has low toxicity to predatory mites. Also increased in use for mite control, in terms of acres treated, were abamectin (up 30 percent) and the newly registered spiromesifen and etoxazole (up 49 percent), while hexythiazox use decreased by 8 percent and acequinocyl decreased 24 percent. Most conventional growers continue to use bifenazate since its introduction in 2003. Acequinocyl is effective against cyclamen mite which is not controlled by bifenazate.

Strawberry production relies on several fumigants. Acres treated with fumigants decreased by 3 percent, including both chloropicrin (down 2 percent) and methyl bromide (down 18 percent), while 1,3-dichloropropene (1,3-D), and metam-sodium use increased by 20 percent and 30 percent respectively. Fumigants usually are applied at higher rates than other pesticide types, such as fungicides and insecticides. Fumigants are applied at high rates, in part, because they treat a volume of space rather than a surface area such as leaves and stems of plants. Thus, the pounds applied are large relative to other pesticide types even though the number of applications or number of acres treated may be relatively small. Fumigants accounted for about 86 percent of all pesticide AIs by pounds applied in strawberries in 2007. Metam-sodium is generally more effective in controlling weeds, but less effective than 1,3-D or 1,3-D plus chloropicrin against soil-borne diseases and nematodes. Because chloropicrin is used in higher concentrations when used in combination with methyl bromide than in combination with 1,3-D, overall use of chloropicrin has decreased despite an increased use of 1,3-D plus chloropicrin.

Carrots

California is the largest producer of carrots in the United States accounting for about 78 percent of the U.S. production of 1,358,068 tons of fresh market and 18 percent of the 345,150 tons of processing carrots in 2007. California produced more than 1.13 million tons of carrots with a total crop value of more than $495 million. California has four main production regions for carrots: the San Joaquin Valley (Kern County), with significant production along the central coast in San Luis Obispo and Santa Barbara counties (Cuyama Valley) and Monterey County; the low desert (Imperial and Riverside counties); and the high desert (Los Angeles County). The San Joaquin Valley accounts for more than half the state’s acreage.

While total acres of carrots harvested decreased by 1 percent, pesticide use (as acres treated) in carrots increased by 15 percent in 2007 after a comparable decrease in 2006, thus returning acres treated nearly to the 2005 level. Pounds of AI applied increased by 1 percent from 2006 to 2007. All major pesticide types increased in terms of acres treated except for fumigants. Pesticides used most (as measured by acres treated) were sulfur, mefenoxam, linuron, iprodione, metam-sodium, pyraclostrobin, copper compounds, chlorothalonil, and trifluralin. The major pesticides with increased acres treated were sulfur, pendamethalin, fenamidone, iprodione, fluazifop-p-butyl, boscalid, pyrethrins, esfenvalerate, chlorothalonil, and 1,3 dicloropropene. The major pesticides with decreased acres treated were trifluralin, copper compounds, mefenoxam, azoxytrobin, and metam-potassium.

Cumulatively, the most used pesticide category for carrots, as measured by acres treated, was fungicides. From 2006 to 2007 acres treated with fungicides increased 21 percent while pounds AI increased by 13 percent. The most applied fungicides in 2007 by acres treated were sulfur, mefenoxam, iprodione, pyraclostrobin (registered in 2003), copper compounds, and chlorothalonil. Alternaria leaf blight, a foliar disease, is generally controlled by iprodione, chlorothalonil, pyraclostrobin, or azoxystrobin. Azoxystrobin and pyraclostrobin are strobilurins with the same mode of action. In terms of acres treated, iprodione increased 14 percent and chlorothalonil increased in use 10 percent while azoxystrobin decreased 27 percent and pyraclostrobin use remained about the same as in 2006. Alternaria leaf blight has become less of a problem recently because of the introduction of resistant carrot varieties. Cavity spot is a major, troublesome soilborne fungal disease that is commonly controlled by applying mefenoxam or metam sodium (a soil fumigant). Growers used less mefenoxam (16 percent) and metam-sodium (2 percent) by acres treated as fenamidone became available since 2006 for control of cavity spot. Powdery mildew is primarily controlled by sulfur, which is inexpensive and especially popular with organic growers. Except for Imperial and Yolo counties, sulfur use increased in all counties in 2007 because weather conditions favored powdery mildew infection.

In terms of acres treated, the main herbicides used in carrot production were linuron, trifluralin, pendimethalin (registered for carrots in 2006), and fluazifop-p-butyl. Linuron, a postemergence herbicide that provides good control of broadleaf weeds and small grasses increased 2 percent. Trifluralin, a preemergence herbicide, used by carrot growers to complement linuron for weed management, declined by 46 percent as pendimethalin has become an effective replacement with less inhibition of carrot root development. In addition, fluazifop-p-butyl, a selective postemergence phenoxy herbicide used for control of annual and perennial grasses increased 29 percent.

Carrot production relies on the fumigants metam sodium, 1,3-D, potassium n-methyldithiocarbamate (metam-potassium), and to a lesser extent, chloropicrin. These fumigants are used at high rates in terms of pounds per acre treated to control soil-borne pests. Methyl bromide is rarely used in carrot production. In 2007, fumigants accounted for about 76 percent of the total pounds of pesticide AIs applied to carrots. This is a 3 percent decline from 2006. Also acres treated with fumigants declined by 4 percent. Use of metam sodium, metam potassium, and chloropicrin declined (2, 49, and –71 percent acres treated, respectively). 1,3 dichloropropene use increased by 18 percent. These fumigants are used to manage nematodes and may provide other benefits such as weed and soil borne disease control. At low to moderate levels of nematode infestation, metam sodium or metam-potassium is usually used. If nematode levels are high, 1,3-D is preferred. 1,3-D usage increased in 2007 probably because of nematode problems and as partial replacement of metam-sodium and metam-potassium which have become more difficult to apply through chemigation due to new regulations, and they are not as effective when shanked in.

Insects are not generally a major problem in carrot production, except for whiteflies that are controlled with esfenvalerate and methomyl. The major insecticides used in 2007 in terms of acres treated were esfenvalerate, diazinon, methomyl, pyrethrins, oil, spinosad, and methoxyfenozide. Acres treated with esfenvalerate increased by 20 percent in 2007. Although generally used against whitefly, it is also used to control flea beetle, leafhoppers and cutworms. Methomyl use by acres treated remained relatively constant after a 92 percent increase in 2006. This carbamate pesticide is effective against cutworms and leafhoppers as well as whiteflies. Diazinon use against cutworms and wireworms remained relatively constant as well. Spinosad use against armyworms, loopers, saltmarsh caterpillars, and cutworms increased by 10 percent. Oil, used both as an insecticide and an insecticide adjuvant, increased by 52 percent. Cyfluthrin, a pyrethroid used to control cutworm and crown root aphids, decreased by 37 percent while pyrethrins used against a wide range of pests increased 2,726 percent. Higher usage may be due to its short half-life in the field, thus requiring multiple applications. Carbaryl use was nearly absent in 2007 as it was in 2006.

VI. SUMMARY OF PESTICIDE USE REPORT DATA 2007 INDEXED BY COMMODITY

The following report presents information of statewide pesticide use for 2007. For each commodity, the chemical that was used, total pounds applied, the number of agricultural applications made, and the amount of commodity treated are summarized.

A summary by commodity is presented in a separate report, *Summary of Pesticide Use Report Data 2007 Indexed by Commodity*. Both versions of the Pesticide Use Report can be purchased from DPR or downloaded from the DPR web site at www.cdpr.ca.gov.
